About the year 1737, on account of his occasional insanity, he was supererded at St. George's church by the late Mr. Keeble, an excellent organist, intelligent teacher, and a worthy man, who, during the life of Roseingrave, divided with him the salary. We prevail'd on him once to touch an organ at Byfield's, the organ-builder; but his nerves were then so unstrung, that he could execute but few of the learned ideas which his mental disorder had left him. His sweetness of temper and willingness to instruct young persons, who were eager in the pursuit of knowledge, tempted us frequently to visit him at Mrs. Bray's, Hampstead, where he resided. His conversation was very entertaining and instructive, particularly on musical subjects. Indeed, his passion for the art never quitted him to the time of his death, which happened in Ireland about the year 1750. The instrument on which he had exercised himself, in the most enthusiastic part of his life, bore very uncommon marks of diligence and perseverance; for he had worn the ivory covering of many of the keys quite through to the wood. In his younger days, when he enjoyed the *mens sana in corpore sano*, he was regarded as having a power of seizing the parts and spirit of a score, and executing the most difficult music at sight beyond any musician in Europe. Indeed, it was said that he could read a music-book, if turned topsy-turvy; but this seems exaggeration of praise, which few can believe, who know the difficulty, without ocular and auricular demonstration. The harmony in the voluntaries, which Roseingrave published, is rendered intolerably harsh and ungrateful by a licentious and extravagant modulation, and a more frequent use of the sharp third and flat sixth than any composer with whose works we are at all acquainted, not excepting Dr. Blow; and his double fugues are so confused by the too close succession of unmarked subjects, that it is impossible, at the end of the performance, to remember what they are. His cantatas, which he published by subscription, being composed on the model of the elder Scarlatti, are the most pleasing of his works; but they were still-born, and never lived to speak in public.

ROSELLE, in *Geography*, a town of Etruria; two miles N. of Grosseto.

ROSEMARKIE, a royal borough town in a parish of the same name, in the county of Ross, Scotland, is situated on the northern shore of the Moray-frith, nearly opposite to fort George. It was constituted a royal burgh by Alexander II. king of Scotland; but in the reign of king James II. it was united with the town of Chanony, (so called from its having been the chanony of Ross, and the residence of the bishop,) and re-incorporated by charter under the name of Fortross, since softened to Fortrose. For some further particulars respecting this town, see FORTROSE. Carlisle's Topographical Dictionary of Scotland, 4to. 1813.

ROSEMARY, in *Botany*. See ROSMARINUS.

ROSEMARY, *Poet's*. See OSYRIS.

ROSEMARY, *Wild*, *Marsh Gistus*. See LEDUM.

ROSEMARY, in the *Materia Medica*. Rosemary has a fragrant aromatic smell, and a bitterish pungent taste. The leaves and tops of this plant are the strongest with regard to their sensible qualities; the flowers are not to be separated from their calyces or cups, as the active matter principally, if not wholly, resides in the latter.

Rosemary gives out its virtues completely to rectified spirit, but only partially to water. The leaves and tops, distilled with water, yield a thin, light, pale-coloured essential oil

oil of great fragraney, though not quite fo agreeable as the rofemary itfelf; from one hundred pounds of the herb in flower were obtained eight ounces of oil; the decoction, thus divelted of the aromatic part of the plant, yields, on being infpiffated, an unpleafant bitterifh extract. Rectified fpirit likewife, diftilled from rofemary leaves, becomes confiderably impregnated with their fragraney, leaving, however, in the extract the greateft fhare both of their flavour and pungency. The active matter of the flowers is fomewhat more volatile than that of the leaves, the greateft part of it arifing with fpirit. Tournefort obferves, that thofe forts of rofemary, which produce neither flowers nor feeds, and which have very hard shrubby ftalks, and long narrow leaves, fmell ftrongly like camphor, and yield on diftilling a large quantity, for the purpofe of obtaining their oil, a portion alfo of real camphor.

Rofemary is reckoned one of the moft powerful of thofe plants which ftimulate and corroborate the nervous fyftem; it has, therefore, been recommended in various affections, fuppofed to proceed from debilities, or defective excitement of the brain and nerves; as in certain head-aches, deafneffes, giddineffes, palfies, &c. and in fome hylterical and dyspeptic fympoms. Dr. Cullen fuppofes the ftimulant power of rofemary infufficient to reach the fanguiferous fyftem; it has however the character of being an emmenagogue, and the only difeafe, in which Bergius itates it to be ufeul, is the chlorofis. In diforders of this kind it has been given in the form of infufion; but it is now fcarcely ever prefcribed, unlefs as an odorous additament to fternutatory powders. The dofe in fubftance may be from grs. x to ℥ij, and from ʒj to ʒifs in infufion. The official preparations are the “oleum rofmarini,” and “fpiritus rofmarini.” It is alfo a principal ingredient in what is known by the name of HUNGARY Water; which fee.

ROSEMARY, *Oil of*, Oleum rofmarini, Lond.; Oleum fummitatum florentium rorismarini officinalis, Edinb.; Oleum herbæ florefcentis roris marini, Dub., is prepared by diftilling twenty-four pounds of the plant, which yield one ounce of a fluid colourlefs oil, the odour of which is lefs agreeable than that of the plant. It depofits cryftals of camphor when long kept. Its fpecific gravity is .934. (See OIL.) This oil is ftimulant; and frequently enters into the compofition of liniments. The dofe, as an internal remedy, may be from ℥ij to ℥vi; but it is fcarcely ever ordered.

ROSEMARY, *Spirit of*, Spiritus rofmarini (Lond.) is obtained by macerating two pounds of fresh rofemary tops in a gallon of proof fpirit, with water fufficient for preventing empyreuma, for twenty-four hours, and then diftilling a gallon in a gentle heat. Spiritus rorismarini officinalis (Edinb.) is prepared by taking two pounds of fresh rofemary tops and eight pounds of alcohol (fpec. grav. .335), and drawing off feven pounds by diftillation in a water bath. Spiritus rorismarini (Dub.) is obtained by diftilling with a moderate fire five pints from a pound and a half of fresh rofemary tops and a gallon of proof fpirit. Oil of rofemary is fufficiently volatile to rife in diftillation with rectified fpirit, which the Edinb. college has, therefore, directed to be ufed. It is a fragrant perfume; and is chiefly ufed in the compound foap liniment or the compound fpirit of lavender. Lewis Mat. Med. Woodv. Med. Bot. Thomfon's Difp.

ROSEMBERG, in *Geography*, a town of Pomerelia; 10 miles S. of Dantzic.

ROSENAU, a town of Pruffia, in Oberland; 16 miles E. of Marienwerder.—Alfo, a town of Moravia, in the circle of Prerau; eight miles E. of Meferitch.—Alfo, a

town of Hungary, near which are mines of gold, copper, quickfilver, and cinnabar; 24 miles W. of Cafchau.

ROSENBERG, a town of Pruffia, in the province of Oberland; 17 miles E. of Marienwerder. N. lat. 53° 39'. E. long. 19° 10'.—Alfo, a town of Hungary, on the Waag, trading chiefly in falt; 18 miles N. of Libeten.—Alfo, a town of Bohemia, in the circle of Bechin; 37 miles S. of Bechin. N. lat. 48° 40'. E. long. 14° 18'.

ROSENBERG, or *Olefn*, a town of Silefia, in the principality of Oppeln; 26 miles N.E. of Oppeln. N. lat. 50° 52'. E. long. 18° 28'.

ROSENBERG, a town of the duchy of Magdeburg; 24 miles S. of Magdeburg.—Alfo, a small Dutch ifland, at the mouth of the Meufe; three miles E. of Briel.

ROSENDAL, a town of Brabant; 15 miles W. of Breda.

ROSENDORF, a town of Bohemia, in the circle of Leitmeritz; fix miles W. of Kamnitz.

ROSENEATH, a town of Scotland, in Dumbartonshire; nine miles W.N.W. of Dumbarton.

ROSENESS, a cape on the S. coaft of the ifland of Pomona. N. lat. 58° 45'. W. long. 2° 42'.

ROSENFELD, a town of Wurtemberg; eight miles S.E. of Sulz. N. lat. 48° 14'. E. long. 8° 43'.

ROSENGAT, a town of Germany, oppofite to Worms.

ROSENHEIM, a town of Bavaria, at the confluy of the Inn and the Manguald; 38 miles W. of Salzburg.

ROSENHOF, a town of the duchy of Holftain; five miles N. of Cifmar.

ROSENIA, in *Botany*, fo called by Thunberg, in honour of two brothers of the name of Rosen, both eminent as phyficians and botanifts, one of whom is well known as the determined and jealous rival of the early fame of Linnæus, though afterwards his friend. (See LINNÆUS.) This gentleman, who died in 1773, aged 67, was profeflor of Medicine at Upfal: the other at Lund. They were natives of Sweden, and knights of the Polar Star.—Thunb. Prodr. præf. n. 59. Nov. Gen. diff. 12. 161. Willd. Sp. Pl. v. 3. 2134.—Clafs and order, *Syngenefia Polygamia Superflua*. Nat. Ord. *Compoftæ Difcoideæ*, Liun. *Corymbifera*, Juff.

Gen. Ch. *Common calyx* of many leaves, imbricated; fcales ovate, obtufe, undivided, fmoth, tranfparent, with a brown, opaque, longitudinal line. *Cor.* compound, radiated; *florets* of the difk perfect, tubular, five-cleft; thofe of the radius female, ligulate, convolute, arched. *Stam.* (in the perfect florets) Filaments five, very fhort; anthers united into a cylindrical tube. *Pift.* (both in the difk and radius) Germen fmall, ftyle thread-fhaped; stigma cloven. *Peric.* none, except the unchanged calyx. *Seed* (in both kinds of florets) angular, fmoth; down, of two kinds of capillary fcales; the two innermoft of the radius generally fetaceous and longeft; the outermoft capillary, united at the bafe into feveral parcels. *Recept.* compofed of lanceolate, membranaceous fcales.

Eff. Ch. *Receptacle* chaffy. *Seed-down* of two kinds, chaffy. *Corolla* radiated. *Calyx* fcariofe.

1. *R. glandulofa*. Thunb. and Willd.—Native of the interior of the Cape of Good Hope. For all that is known of this folitary fpecies of *Rofenia*, we are indebted to the following defcription of Thunberg. “*Stem* shrubby, round, fmoth, wavy, erect, much branched, generally more than two feet high. *Branches* and *branchlets* alternate, three or four together, in a cluster, fpreading, ftriated: the branchlets lateral, very fhort, leafy. *Leaves* fomewhat clustered, approximating, feffile, ovate, obtufe, undivided, flightly concave,

cave, chiefly glandular at the margin, downy, thickish, imbricated, half as long as the nail. *Flowers* capitate, terminal."

ROSENOU, in *Geography*, a town of Pomerania; eight miles S.S.E. of Cofslin.

ROSENTHAL, a town of the principality of Hesse; eight miles N.N.W. of Marburg.—Also, a town of Westphalia, in the bishopric of Hildesheim; three miles S.W. of Peina.—Also, a town of Prussia, in the palatinate of Calm; eight miles N.E. of Bretchen.—Also, a town of Bohemia, in the circle of Bechin; three miles N. of Rosen-berg.

ROSEOLA, in *Medicine*, a term appropriated, in the nomenclature of cutaneous diseases devised by the late Dr. Willan, to a rose-coloured rash or efflorescence upon the skin, which is variously figured, without any elevation of the surface, and not communicable by contagion.

This rash is of little importance in a practical view, because it is mostly a mere concomitant of different febrile complaints, and requires no deviation from the treatment adapted to their relief; but as it is sometimes mistaken both for scarlet fever and measles, which are contagious and often dangerous diseases, so it ought to be known, and its varieties discriminated. The appellation of roseola is to be found in the works of some of the early modern writers; but it was applied somewhat indiscriminately to every red rash, to scarlet fever, measles, &c. Fuller, in his *Exanthematologia*; p. 128, speaks of a sort of rose-rash, as a flushing all over the body, like fine crimson, which, he says, is void of danger, and "rather a ludicrous spectacle, than an ill symptom."

Seven varieties of roseola were distinguished by Dr. Willan under the following appellations.

1. The roseola *æstiva*, so called from its usual occurrence in summer, is sometimes preceded for a few days by slight febrile symptoms, such as pains in the head and limbs, lassitude, and listlessness. The rash appears first on the face and neck, and, in the course of a day or two, is distributed over the rest of the body, producing a considerable degree of itching and tingling. The mode of distribution is into separate small patches of various figure, but of larger and more irregular forms than in the measles, with numerous interstices of the natural skin. It is at first red, but soon assumes the deep roseate hue peculiar to it. The fauces are tinged with the same colour, and a slight roughness of the tonsils is felt in swallowing. The rash continues vivid through the second day; after which it declines in brightness, slight specks only of a dark red hue remaining on the fourth day, which, together with the constitutional affection, wholly disappear on the fifth.

Not unfrequently, however, the rash is partial, extending only over portions of the face, neck, and upper part of the breast and shoulders, in patches, very slightly elevated, and itching considerably. In this form the complaint continues a week or longer, the rash appearing and disappearing several times; sometimes without any apparent cause, and sometimes from sudden mental emotions, or from taking wine, spices, or warm liquors. The retrocession of the rash is usually accompanied with disorder of the stomach, head-ache, and faintness, which are immediately relieved on its re-appearance.

This species of roseola usually occurs in the summer season, and particularly in females of an irritable constitution. The patients commonly ascribe it to sudden alternations of heat and cold, and especially to having drunk cold liquors, when perspiring after exercise. Sometimes it occurs in connection with bilious diarrhœa, cholera, dys-

entery, or other bowel complaints of the hot season; and sometimes it appears after much fatigue.

Very little medical treatment is required for this eruption, which is generally alleviated by moderate diet, from which every thing heating is excluded; and by the use of acidulated drinks, with occasional laxative medicines. The complaint is never dangerous, except from the sudden repulsion of the eruption, in consequence of exposure to very chill air, or of the application of cold water; in which case violent disorder has taken place in the head, stomach, or bowels of the patient, as happens under similar circumstances in other eruptive diseases, such as measles, the red gum, &c.

2. The roseola *autumnalis* is not uncommon in children of five, or from that to ten years of age, in the autumn. It occurs in distinct patches, of an oval or circular shape, which occasion no elevation of the cuticle, and gradually increase to about the size of a shilling. Their hue is of a dark damask red; so that at a distance the skin appears as if stained with the juice of black cherries or mulberries. They are usually diffused over the arms, seldom on the face and body; and they continue about a week, being sometimes, but not always, succeeded by desquamation. This eruption is not accompanied by much itching or tingling, nor is there any symptom of general disorder, except a whiteness of the tongue. It is generally removed in a short time by the exhibition of the diluted sulphuric acid internally.

3. The roseola *annulata* appears on almost every part of the surface of the body in rose-coloured rings, which have central areas of the usual colour of the skin; and it likewise slightly affects the throat. The rings are at first from a line to two lines in diameter; but they gradually dilate, leaving a larger central space, sometimes to the diameter of half an inch; and excite, especially in the night, a troublesome sensation of heat, and of itching or prickling. The duration of the eruption is very uncertain; in some cases it commences with shivering succeeded by heat, and is attended with head-ache, flushing of the face, sickness at the stomach, and pains in the limbs; it then continues four or five days, and disappears as the febrile symptoms decline. In other cases, which are without fever, the complaint is of long duration; the efflorescence usually fades in the morning, and returns in the evening or night, the rings becoming vivid, and sometimes a little elevated. If the rings should disappear, or be very faint in colour for several successive days, the patient becomes affected with pain in the stomach, sickness, vomiting of bile, great languor, giddiness and aching in the limbs. These symptoms are alleviated or removed by the use of the warm bath, after which the efflorescence generally returns. Sea-bathing and the mineral acids afford much relief to the more chronic forms of this species of roseola.

The annular roseola appears to be sometimes connected with an irregular state of the catamenia in women, and with gouty and rheumatic complaints in both sexes. It sometimes succeeds to a fit of the gout, and we have seen it appear as the precursor of a fit, which immediately followed its disappearance.

4. The roseola *infantis* affects children during the period of teething, in fevers, and in disorders of the bowels, and the rash is usually so close and full as to leave very small interstices of the natural hue of the skin. It is very irregular, however, in its appearance and progress, sometimes continuing only for a night; sometimes appearing and disappearing for several successive days, being attended with symptoms of violent irritation; and sometimes arising in  
single,

single, but numerous and coalescing, patches, of about the size of a sixpence, which continue for several days, and terminate in scurf. This rash, where it is pretty generally diffused, is often mistaken, as Dr. Underwood has remarked, for measles and scarlet fever. Whence it is necessary, that its character should be well known to medical practitioners; although it requires no specific treatment, but usually disappears under the employment of remedies calculated to relieve the bowel complaints, painful dentition, and other febrile affections, with which it is so frequently connected.

5. The roseola *variolosa* occurs previous to the eruption of the small-pox, when produced by an inoculation, in the proportion of about one case in fifteen, according to observations made at the Small-Pox Hospital. It usually appears on the second day of the eruptive fever, which is generally the ninth or tenth after inoculation, and is deemed by inoculators a certain prognostic of a small and favourable eruption of the small-pox. It does also occasionally occur in the natural small-pox, on the third or fourth day, and with a moderate and favourable eruption of pustules; but it is much more rare than in the inoculated disease.

This rash is first observable on the arms, breast, and face: on the following day it extends over the trunk of the body and the extremities. Its distribution is various; sometimes in contiguous semicircles; sometimes in longitudinal irregular patches, with small distinct dots intermixed; and in a few cases, all these appearances being combined, it forms an almost continuous redness over the body, and is in several parts slightly elevated above the surface, as in the measles. It is not easily repelled by cold air, or cold drinks, as the early inoculators apprehended; and is aggravated by the confinement and sudorific medicines which they recommended.

These roseolous efflorescences, antecedent to the eruption of small-pox, were occasionally observed by the first writers on the disease; and both by them and subsequent authors were deemed to be measles, which were said to be converted into small-pox.

6. Roseola *vaccina*. An efflorescence which is somewhat diffuse, like the variolous rash, but appears generally in congeries of dots and small patches, a little elevated, takes place in some children on the ninth and tenth day of vaccination, at the place of inoculation, and at the same time with the areola that is formed round the vesicle; and from thence it spreads irregularly over the whole surface of the body. But this does not occur nearly so often as after variolous inoculation. It does not continue vivid above forty-eight hours; and is usually attended with a very quick pulse, a white tongue, and great restlessness. Some vaccinators attach little importance to it; others think it a favourable circumstance, as denoting that the skin and constitution have been fully affected by the cow-pock.

7. Roseola *miliaris*. This rash often accompanies an eruption of miliarial vesicles, with fever, where much heat and sweating have been excited. (See MILIARY FEVER.) It occurs occasionally, however, in the continued fevers of this country, where neither a miliarial eruption nor profuse sweating had preceded it, and does not appear to be an unfavourable symptom. See Willan on Cutaneous Diseases, p. 433, et seq., and Bateman's Pract. Synopsis of Cutan. Dif. p. 96, 3d edit. See also Underwood, on the Dif. of Children, vol. i. p. 87.

ROSES, *Islands of Two*, in *Geography*, two small islands in the Indian sea, near the coast of Africa. S. lat. 17°.

ROSES. See ROSAS.

ROSETO, a river of Naples, which runs into the gulf of Tarento, N. lat. 40° 2'. E. long. 16° 40'.

ROSETTA, ROSSETTA, or *Rafchid*, a town of Egypt, of considerable size and population, founded in the eighth century, as some have said; though Elmacin informs us, that it was built during the reign of Elmetouakkel, caliph of Bagdad, towards the year 870 of our era, and under the pontificate of Cosma, patriarch of the Jacobites at Alexandria. Others date its foundation at a much later period; and Belon, who travelled in Egypt in 1530, says that this town was much smaller than Faoué, but at present it is much larger. It has borne the Arabic name Rafchid ever since the time of Edrissi the geographer, in 1153, and of this the Europeans have made Rosetta or Rossetta. Some have erroneously asserted, that it was built on the spot where Canopus was situated; whereas the Canopic branch of the Nile is the lagoon of Maadié, and the ruins of Canopus are at Aboukir. Rosetta affords no trace of antiquity; nevertheless it is certain, says Sonnini, that it cannot be far from the place where stood Metelis or Metilis, of which Strabo and Ptolemy make mention, and which was on the western bank, and near the mouth of the Bolbitic branch of the Nile. The heaps of sand, which this river is continually accumulating, no longer permit vessels to reach as far as Faoué. Although Rosetta was built at the mouth of the river, it is already two leagues from it. According to Abulfeda it was very inconsiderable in the 13th century; nor was it much increased for 200 years after this time. But when the Ottomans added Egypt to their conquests, they neglected the support of the canals. Thus, the canal of Faoué ceasing to be navigable, Rosetta became the emporium of the merchandize of Alexandria and Cairo. Commerce soon made it flourish, and it is at this day one of the handsomest towns in Egypt. It extends along the western bank of the Nile, and is above a league in length, by a quarter of a mile in breadth. Although it has no remarkable place, nor any one street quite regular, yet all the houses, being built with terraces, and well disposed, have, by Savary's description of it, an air of cleanliness and elegance, which is very agreeable; to which Sonnini adds, that here are seen long streets formed by two rows of shops, in which are found all sorts of goods; the necessaries of life being very plentiful, and procured at a low price. Within the houses are spacious apartments, well ventilated by a great number of windows, which are always open. The blinds and transparent linen, which they stretch over them, keep out the rays of the sun, afford a moderate light, and mitigate the excessive heats. The only public buildings worthy of notice are the mosques, with their lofty minarets, of light architecture, and constructed with much boldness. They thus produce a very picturesque effect in a town where all the roofs are flat, and throw great variety into the picture. The houses in general have a view of the Nile, and of the Delta, which form a most magnificent spectacle. The river is always covered with vessels, mounting and descending with oars, or under sail. The tumult of the harbour, the joy of the mariners, their noisy music, exhibit a moving and animated scene. The Delta, that immense garden, where the earth is never weary of production, furnishes the whole year a succession of harvests, of vegetables, of flowers, and of fruits; various species of cucumbers and delicious melons, the fig, the orange, the banana, the pomegranate, of the most exquisite flavour. To the north of the town are gardens, where lemon and orange trees, date trees, and sycamore trees, are planted at random; by their foliage affording an arch impenetrable to the rays

of the sun, and by their flowers rendering the shade of these groves delightful. The houses of Rosetta, says Sonnini, are much better built, in general, than those of Cairo: its situation upon the banks of the river; the view of the Delta, which presents, as Savary describes it, the delightful prospect of the most beautiful culture, the perfumed groves in its neighbourhood, and its pure and wholesome air, have most deservedly procured for it the name of the "garden of Egypt." Commerce constitutes the principal wealth of the inhabitants of Rosetta. The importation of foreign merchandize to Cairo, and of the productions of Egypt into the port of Alexandria, employs a great number of mariners. (See BOGHASS and SCHERM.) The bar of the Nile is totally shut during two months of the year, and the commerce of Alexandria is interrupted. But if all the ships in Egypt were to perish, the Ottoman government, says Savary, would not remove one inch of ground of the canal of Faoué to render it navigable. It suffers every thing to go to ruin, and repairs nothing.

In the town of Rosetta a profound silence reigns, uninterupted by the noise of any carriage. The inhabitants move with gravity through the streets, clad in long robes which hang down to their heels. Their heads are covered with heavy turbans, or bound round with a schale or shawl, which is a long piece of stuff made of silk or wool. The girdle is made use of by both sexes. The citizen is armed with a knife, the soldier with a sabre, and a pair of pistols. The women of the lower class, whose dress consists of a large blue shift, and a long pair of drawers, have their faces covered with a piece of linen, with holes opposite to the eyes. The rich wear a large white veil, with a cloak of black silk, that wraps up their whole body. But though they are thus masked, they are not scrupulous in making signs, nor in ogling.

The most ordinary pastime here is smoking and drinking coffee. From morning to night the inhabitants have their pipes in their mouths; at home, in each other's houses, in the streets, on horseback, they keep their pipe lighted, and the tobacco-bag is hung at their waist. If the inhabitants of Rosetta be less barbarous, says Sonnini, than those of the other parts of Egypt, they are not less ignorant, less superstitious, nor less intolerant. We find among them, although with shades more softened down, the same roughness of character, the same implacable aversion towards the nations of Europe, and disposition to insult both Christians and Jews, the same revengeful disposition, in a word, the same treachery; and they are addicted to the same shameful vices, some of which we cannot name.

The country round Rosetta is an immense surface, without a mountain or hill, intersected by innumerable canals, covered with harvest and a variety of trees, which winter never strips of their leaves. The soil is a black mould, the fertility of which is inexhaustible. The chief article of cultivation is rice, called in the vicinity of Rosetta "sultani," which is sown from the month of March to that of May, transplanted on the banks of the Nile, and on the borders of the canals at the end of July, and cut in November. (See EGYPT.) Rice forms a principal article of exportation, which they dry by spreading upon the terraces of the houses and in the public squares; and to this operation is attributed the multitude of gnats, with which the town and the inside of the houses are filled at the time when it is performed.

Rosetta, besides being the great emporium of the trade that is carried on between Cairo and Alexandria, has some branches of commerce peculiar to itself; such as spun-

cotton, dyed red, which is drawn from the adjacent districts; dressed flax, linen cloths, silk dyes for the eastern dresses, &c. The flax of the country, which is long, soft, and silky, would make beautiful linen, if they knew how to employ it; but the spinsters are very inexpert, and the thread they make is clumsy, hard, and uneven. The linens they bleach serve for the table; the rest, dyed blue, is employed for the clothing of the people. In Rosetta there are store-houses of natron, and manufactories where it is used. (See NATRON.) Most of the merchants of this town are Turks or Syrians, and some from Barbary. The Copts are numerous, together with some Arabs. The command of the town is vested in an officer of the Mamlouks, who bears the title of Aga. About a league from the sea, northward of Rosetta, are two castles, one on the western bank of the Nile, and the other on the opposite bank of the river, constructed to defend the entrance of the river. The former, which is ascribed to St. Lewis in the time of the crusades, is almost entirely demolished; and the few cannon which remain in it are unfit for service. These two forts, though inconsiderable, and in a ruinous state, would be sufficient to stop vessels from entering the river, if the Turks knew how to make use of cannon; but here they have no occasion for it; as nature has guarded the mouth of the Nile, by raising a dangerous bar, called the *Boghafs* or *Bogaz*, which is the terror of mariners. About half a league to the south of Rosetta is a tower, called the tower of Canopus, from the erroneous supposition that Rosetta is on the site of the ancient Canopus. This tower has been built, in modern times, upon a hillock of sand, which at this place forms the W. bank of the Nile. It is square, and partly demolished. In the lower part the inhabitants of this district shew the opening of a subterraneous passage, which, as they say, led to Alexandria. Near the top of the same is presented a general view of the country, having no bounds except those which nature has prescribed; and near its foot, close to the edge of the Nile, stands a mosque, consecrated to a holy Mussulman, called "Abou-Mandour," which signifies father of the light. This saint, if he be the father of the light, is also the terror of the sands, as, but for him, they would long ago have overwhelmed Rosetta, and added it to their dreary domain. Opposite to this mosque, upon the E. bank of the Nile, are two or three houses, called Maadée, because they stand at the place facing the usual passage to the Delta. On the west bank, at a short distance above Abou-Mandour, is Dgeddiè, a considerable village, in the environs of which a great number of vine-plants grow in the sand; from hence Rosetta and Alexandria are supplied with grapes.

At the foot of the tower above-mentioned, a large semicircular basin announces a port, which has been choked up by the sand. In digging at the bottom of this hillock, twenty beautiful marble pillars were discovered by a Turkish merchant, who was stripped of his fortune by the Beys, from an imagination that he had carried off a treasure from this place. M. d'Anville suspects that the ancient Bolbitina must have been at a very small distance from the spot on which Rosetta now stands. The ruins now mentioned seem to confirm his conjecture; as they are at the extremity of a town, and can only belong to the Bolbitina spoken of by Steph. Byz. and which gives its name to one of the branches of the Nile. This place is very picturesque; the tower, falling into ruins, is surrounded by tombs, and to the westward is a desert plain, whose burning extent the eye cannot look over without horror; but on the E. the contrast is very striking, presenting a majestic river, and the Delta,

uniting most profusely the graces of the spring, the beauty of the summer, and the rich luxuriance of the autumn.

Sir R. Wilson has given us a picture of Rosetta, very different from that which we have above exhibited. He says, it is built of a dingy red brick, and that a great part of the town is in ruins, many of the houses having been pulled down by the French for fuel. The streets are not more than two yards wide, and full of wretches, which the pride of civilization revolts at acknowledging to be human. The number of blind persons is prodigious; nearly every fifth inhabitant having either lost, or having some humour in, his eye. The erysipelas, the dropsy, the leprosy, the elephantiasis, and *lusi naturæ*, constantly offend the sight. Filth, mosquitos of the most dreadful sort, vermin of every kind, women so ugly, that, fortunately for Europeans, their faces are concealed by a black cloth veil, in which are cut two eye-holes; stench intolerable; houses almost uninhabitable:—these form the charms of Rosetta, and Savary's garden of Eden. The quay, however, is allowed to be a handsome object, and might be made noble. The baths are represented as horribly disgusting. Dr. Wittman, cited also by Crutwell, observes, that though it contains but few striking public edifices, Rosetta must be considered as a handsome place by those who have been accustomed to mud walls and sandy deserts; the mosques and their minarets, as well as their houses, built with bricks, plattered over and white-washed. The population he estimates at 8 or 10,000, but from the number of empty houses, it appeared capable of containing at least treble that number. In 1807, the British were defeated here, with considerable loss, by the Turks; 90 miles N.W. of Cairo. N. lat. 31° 24'. E. long. 30° 40'. Savary. Sonnini. Niebuhr.

ROSETTE, in *Military Language*, an ornamental branch of ribbands, or cut leather, which is worn both by officers and soldiers in the British service, on the upper part of their cues.

ROSETTES, two small bunches of ribbands that are attached to the loops by which the gorget of an officer is suspended upon his chest. The colour of the ribband must correspond with the facing of the uniform. The French use the same term.

ROSETTI, DONATO, in *Biography*, an ingenious Italian, who flourished in the 17th century, but of whose personal history little is known. He was a native of Leghorn, where he was probably educated, and was so successful in the cultivation of the sciences, that at a very early age he was considered as completely qualified to teach mathematics and the elements of philosophy in different universities. While he was professor of logic at Pisa, he published a treatise relating to the system of the earth, which was well received. The title of this work was "Antignome fisico Mathematiche con il nuovo Orbe e Syste'ma terrestre." This was followed by "A Collection of physico-mathematical Instructions;" "A Treatise on the Composition of Dutch Glasses, and Glass Drops;" "A Collection of physico-mathematical Demonstrations" of propositions which he had undertaken to prove. In his "Antignome," he maintained that the number of senses was eleven: this increase he made out by considering the different modes in which we touch bodies as so many different senses, and endeavouring to shew that the perceptions arising from them cannot properly be ascribed to the sense of feeling in general. He was the author of another treatise, entitled "Polista fedele," intended to explain the inclination of bodies to unite at their poles, and various phenomena respecting their hardness, their elasticity, their extension, and the causes which convert solids

into fluids. It is not known when this philosopher died: he was living at Pisa in the year 1678.

ROSETTI, ANTONIO, chapel-master to the duke of Mecklenburg Schwerin, born, according to Gerber, at Milan, in 1744; but we have better authority to say that he was a native of Bohemia, and a disciple of the great Haydn at Vienna, where, in 1755, he was a violinist in the imperial chapel, and afterwards in the service of count Althan, 1780. Since that time he has been a voluminous publisher at Hamburg and Leipzig, of pieces for the piano-forte, with and without a violin accompaniment, of symphonies for a full orchestra, on the plan of his master Haydn, flute concertos, &c. Some of his symphonies, when performed at the concerts in England, while Haydn was in this country, we thought written with force, and abounding with fire and new passages.

ROSEWAY PORT, in *Geography*, a populous sea-port town on the S.E. coast of Nova Scotia, N.E. by E. of cape Negro and Harbour.

ROSEWAY Island, an island that lies at the mouth of Port Wager, on the S.E. coast of Nova Scotia.

ROSEWELL, THOMAS, in *Biography*, a Presbyterian divine, was born in Somersetshire about the year 1630, and was educated at Oxford. After leaving the university, he was presented to the living of Strode, in his native county, from which he was ejected in the year 1662, by the Bartholomew act. In 1674 he officiated with a Non-conformist congregation at Rotherhithe; and in the year 1684 he was arrested on a charge of high treason: on this charge he was tried in the court of king's bench, November 8th, before the infamous Jefferies. The indictment was on words said to have been delivered from the pulpit, and the witnesses were three women of abandoned characters, of whom the chief was afterwards set in the pillory for perjury. The trial lasted seven hours, and Mr. Rosewell behaved with all the decency and respect that could have been expected, and made a defence that was applauded by all who heard him. The women, says bishop Burnet, could not prove, by any circumstance, that they were even present at the meeting, and the words to which they swore were so gross, that it was not to be imagined that any man in his wits would have made use of them in a mixed assembly; yet Jefferies urged the matter with his usual vehemence. He laid it down as an axiom, concerning which there could be no controversy, that all preaching at conventicles, as he was pleased to call dissenting places of worship, was treasonable, and that this ought to dispose the jury to believe any evidence upon that head. The jury accordingly found the prisoner guilty. As soon, however, as the trial was over, sir John Talbot, who was present at it, went to the king, and urged it on his majesty, that if such evidence was admitted, as had appeared against Mr. Rosewell, no one of his subjects would be safe. Upon this, when Jefferies soon after came into the royal presence, with an air of exultation and triumph, to congratulate his majesty on the conviction of a traitor, the king afforded him a cool reception, which mortified him exceedingly, but at the same time it gave a complete turn to the bent of his mind; so that when the court met to hear Mr. Rosewell's counsel, who moved for an arrest of judgment, this judge, who was as mean as he was corrupt and cruel, assumed a tone of moderation, and strongly recommended to the king's council caution and deliberation where the life of a man was depending. The prisoner was, in the end, pardoned. He died in 1691. Neal's Hist. vol. iv.

ROSHAN, or ROSHAWN, in *Geography*, a country of Asia, situated between Meckley and Arracan, between

92° and 95° E. long., and 21° and 23° N. lat.; about 120 miles in length, and 80 in breadth. See ARRACAN.

ROSHEIM, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the district of Barr; 15 miles S.W. of Straßburg. The place contains 3355, and the canton 12,017 inhabitants, on a territory of 227½ kilometres, in 15 communes.

ROSHOVER, a township of Pennsylvania, in West-minter county, containing 1786 inhabitants.

ROSTCRUCIANS. See ROSYCRUCIANS.

ROSIENNE, in *Geography*, a town of Samogitia, in which the diet and court of judicature are held; 76 miles S of Mittaw. N. lat. 55° 30'. E. long. 41° 57'.

ROSIERE, LA, a small island near the S.W. coast of the island of Jersey; 1 mile E.S.E. of Noirmont Point.

ROSIERE, a town of France, in the department of the Somme, and chief place of a canton, in the district of Montdidier. The place contains 2760, and the canton 13,812 inhabitants, on a territory of 120 kilometres, in 21 communes.

ROSIERES *aux Salines*, a town of France, in the department of the Meurte, on the Meurte, formerly celebrated for its salt-works; 6 miles W. of Luneville.

ROSIERS, a town of France, in the department of the Mayne and Loire, on the Loire; 7 miles N.W. of Saumur.

ROSIERS, *Cape*, the S. limit of the mouth of the river St. Lawrence; being the easternmost point of the district of Gaspee, in Lower Canada. N. lat. 48° 56'. W. long. 63° 40'.

ROSIGNANA, a town of Etruria; 13 miles S.E. of Pifa.

ROSIL, in *Rural Economy*, a term applied to such land as is neither light nor heavy, being a medium between sand and clay; it is sometimes written *rosfills*.

ROSILLY BAY, in *Geography*, a bay on the S. coast of Wales. N. lat. 51° 32'. W. long. 4° 16'.

ROSIN, JOHN, in *Biography*, an antiquary, was born at Eifnach in 1551, and died of the plague in 1626. He was author of "Antiquitatum Romanarum," a work of high reputation, of which the best edition is that of Utrecht, in 1701.

ROSIN, *Resina*, in *Pharmacy*. See RESIN.

ROSIN is particularly used for a resinous matter prepared from the juice of the pine-tree; in ordinary use for the making of ointments, plasters, and for other purposes.

For the method of procuring it, see PINE, and TURPENTINE.

ROSITO, in *Geography*, a town of Naples, in Calabria Citra; 16 miles N.E. of Cassano.

ROSITO, *Cape*, a cape on the east coast of Calabria. N. lat. 40° 5'. E. long. 16° 40'.

ROSKOPF, a mountain of Austrian Swabia; 1 mile S.E. of Schonau.

ROSLAND, in our *Old Writers*, heathy land, or ground full of ling; also watery and moorish land.

ROSLAVL, in *Geography*, a town of Russia, in the government of Smolensk. N. lat. 54°. E. long. 32° 50'.

ROSLAW, a river of Saxony, which runs into the Elbe, opposite to Dessau.

ROSLDORF, a town of Austria; 6 miles S.W. of Ehrnsprunn.

ROSLYN, ROSLIN, *Roslyn*, or *Rosklyn*, a village in the parish of Lathwade, and county of Midlothian, Scotland, is about six miles S.S.W. from Edinburgh. This place is much celebrated on account of its castle and chapel, and for the romantic character of the scenery in its immediate vicinity. An excursion to Roslyn is one of the fa-

vourite summer recreations of the inhabitants of the northern metropolis; and no traveller of taste leaves that part of the kingdom, without contemplating its beauties. The castle is seated on a bold and lofty rock, overhanging the river North-Esk, which dashes over a rugged channel at the base, in a semicircular sweep; and the precipitous banks are covered with a profusion of wood. Only a very small portion of the ancient building is now standing; but a modern mansion has been erected on part of the old walls. It is uncertain when this castle was built; but that event most probably occurred about the commencement of the 12th century, when William de Sancto-Clere (son to Waldernus de St. Clere, who came to England with William the Conqueror) obtained a grant of the barony of Roslyn from the Scottish king, Malcolm Canmore. No mention of it is made in history, however, till the reign of James II. of Scotland, when sir William Hamilton is stated to have been confined here, for joining the rebellious standard of earl Douglas. In 1554 it was set fire to, and in great part demolished, by the forces of king Henry VIII. The St. Clere family, or, as the name is now spelt, St. Clair, was anciently of great note in Scotland. Their possessions were very extensive, and their titles numerous, being earls of Caithness and Orkney, lords of Nithsdale, and barons of Pentland, Couf-lande, Cardain, Saint-Clair, Herbertshire, Hertford, Grahamshaw, Kirkton, Cavers, Newborough, and Roxburgh. Their affluence and power exceeded that of most contemporary nobles, either in England or Scotland; and they lived in a style of magnificence and splendour, which even the Scottish monarchs were scarcely able to rival. James II. conferred upon them the honour of being hereditary patrons and grand masters of masonry in Scotland; privileges which they continued to enjoy for several generations.

The chapel of Roslyn occupies the summit of a hill above the castle. It was founded in the year 1446, by William Saint Clair, earl of Caithness and Orkney, for a provost, six prebendaries, and two singing boys; and was endowed by him with considerable landed possessions. He did not, however, live to complete his undertaking, notwithstanding he spared neither trouble nor expence to effect this purpose before his death, which happened in 1479. From a manuscript memoir of the house of Douglas, deposited in the library of the Faculty of Advocates at Edinburgh, we learn many curious particulars relative to the building of this chapel. It is there said, that the founder "caused artificers to be brought from other regions and forraigne kingdomes, and caused dayly to be abundance of all kinde of workemen present;" and it is subsequently added, "and to the end the worke might be more rare, he caused the draughts to be drawn upon Eastland boards, and made the carpenters to carve them according to the draughts, and then gave them for patterns to the masons, that they might thereby cut the like in stone." The present building is generally supposed to have been intended only for the choir of a large collegiate church, which, according to tradition and probability, it was the design of the founder to have erected. Though in a mutilated state, its architecture is unique, and combines, according to Mr. Gandy, "the Egyptian, Grecian, Roman, and Saracenic styles;" and exhibits the arch "in all its possible forms and principles." This structure measures in the interior 68 feet in length, and 35 in breadth. The exterior is supported by 21 buttresses, surmounted by pinnacles, each differing from the others in its ornaments. Two of these buttresses have double pinnacles, the outer shafts of which are smaller than the inner, with which they are connected by flying abutments. Similar

members also unite the larger pinnacles with the upper part of the chapel. The eastern end displays five buttresses, with four pointed windows intervening, all of uniform size and style, though varying somewhat in the tracery work with which they are ornamented. Each window is divided by a stone mullion, faced, both internally and externally, with double columns; and the transept of the arch is decorated with half figures of persons in the attitude of supplication, and with different kinds of foliage. On the north and south sides of the chapel, in the lower compartment, are five windows of a similar kind; also a pointed arched door-way, recessed under a larger semicircular arch, above which is an irregular triangular window, highly ornamented. Another tier of windows, on each side, gives light to the upper part of the building; but these are now much mutilated, having lost their mullions, tracery, &c. Between every two windows are two canopied niches, and a bracket, which appear to have been designed for statues. This portion of the building is supported by two opposite ranges of five arches each, separating the body of the chapel from the side aisles; beyond which, at the east end, there are two columns, and two more in the centre between them, all of them supporting stone beams, exhibiting a great variety of sculptural ornaments. One of the centre pillars is wreathed, and is popularly called the apprentice's pillar, from a tradition respecting its execution by an apprentice of the mason of the structure; who, it is said, finding himself unable to understand the model furnished to him, went abroad for instructions, during which time the work was accomplished by the apprentice. It is singular that a similar story is told of some of the best sculptures in Melrose abbey; and we believe, also, of a much later production of art, the statue of king Charles II. in the Parliament-square at Edinburgh. Two heads in the chapel are said to represent the master and the apprentice. The former is shewn as frowning, and the latter with a scar or indentation on the forehead, to denote that he was murdered by his master, through envy of his superior genius. At the east end of the chapel are four altars, dedicated to different saints. "Of arches," says Mr. Britton, in his *Architectural Antiquities*, "there are more than thirteen varieties to be found in this building. A flat or segment beneath the roof of the aisles, and over the door to the sub-chapel; semicircular in the vault of the roof, and over the entrance doors; groined, acutely pointed over the western aisle; flat pointed between the centre and side aisles; sharp pointed in the lower windows; ogee to the piscinas; flattened, and latest of the pointed style, inside of the door-way, fourth side; half segment in the flying buttresses; counter arch in the triangular windows; flat arch and segment joined in a door in the vault; several arches of various forms in the windows, niches, and canopies, also in the battlements." The vault above-mentioned is the burying-place of the family of the Sinclairs. The soil of it is so dry, that bodies have been found entire 80 years after their interment. They were formerly buried in armour, and without a coffin. "The late Roslin," says father Hay, in his MS. memoirs, "was the first that was buried in a coffin, contrary to the sentiments of James VII., who was then in Scotland;" and he adds, "that the great expence my mother was at in burying her husband, occasioned the sumptuary acts that were made in the next parliament." There was formerly a superstitious story relative to this chapel current among the common people in the neighbourhood. They believed that, previous to the death of any member of the Saint Clair family, the chapel was to be seen in flames, without sustaining any injury. This superstition is alluded to by Mr.

Scott, in his "Lay of the Minstrel," in the following beautiful lines:

"Seem'd all on fire that chapel proud,  
Where Roslin's chiefs uncoffin'd lie,  
Each baron, for his sable shroud,  
Sheath'd in his iron panoply.  
Seem'd all on fire, within, around,  
Deep sacrilicy, and altar's pale;  
Shone every pillar foliage bound,  
And glimmer'd all the dead men's mail.  
Blaz'd battlement and pinnet high,  
Blaz'd every rose-carv'd buttress fair,  
So still the blaze, when fate is nigh,  
The lordly line of high St. Clair."

The village of Roslyn was anciently a place of considerable importance. King James II. constituted it a burgh of barony in the year 1456, and granted to the inhabitants a weekly market and a fair; but these privileges are now abandoned. The fields immediately contiguous are celebrated in history as the scene of three sanguinary engagements betwixt the English and Scotch; all fought on the same day, the 24th of February, 1303. The particulars are thus narrated by the Scottish historians. During a truce, Ralph Conroy, treasurer to Edward I., invaded Scotland at the head of thirty thousand men. With a view to plunder, he divided his forces into three bodies; and having reached the vicinity of Roslyn, encamped them in three distant stations. On being apprised of this invasion, sir John Cumming and sir Simon Frazer marched with 10,000 men to watch the motions of the enemy; and finding the first division unprepared, attacked and routed it with great slaughter. The second division coming up immediately after the battle, shared the same fate; as did likewise the third division, which appeared in a similar manner at the close of the second action. This engagement excited much interest both at home and abroad; and is ranked among the noblest efforts of Scottish bravery. About half a mile lower down the Esk, is situated the house of Hawthornden, remarkable not only for its having belonged to Drummond, the celebrated poet and historian, but also for the caves under it. There are various conjectures as to the original intention of these subterraneous cavities. Stukeley has given credit to a fabulous tradition, that they were strong holds of the Pictish kings; and accordingly one cave is called the king's gallery, another the king's bed-chamber, and a third the guard-room. Setting aside this groundless tradition, the most probable opinion is, that they were resorted to as places of refuge during the destructive wars between the English and Scotch. Detached from the principal caves is a smaller one, called the Cypress grove, where Drummond is said to have composed many of his poems. It was in these caverns that the famous sir Alexander Ramsay, one of the ancestors of the Dalhousie family, who performed such exploits of valour in the contest for the crown between Bruce and Baliol, used to conceal himself. Here he was resorted to by the young warriors of his day, who considered it as a necessary part of military education to have been of his band. From thence he sallied forth, as occasion presented itself, and attacked the English, then in possession of Edinburgh. The Statistical Account of Scotland, by sir John Sinclair. *Architectural Antiquities of Great Britain*, vol. iii. 4to. by John Britton, F.S.A. *A Companion and useful Guide to the Beauties of Scotland and the Hebrides*, &c. by the Hon. Mrs. Murray Aust, of Kenfington, 2 vols. 8vo. Lond. 1810.

ROSMARILHAL, a town of Portugal, in the province of Beira, on the borders of Spain; 8 miles W. of Alcantara, in Spain. N. lat. 39° 33'. W. long. 6° 50'.

ROSMARINUS, in *Botany*, so called from *ros*, dew, and *marinus*, alluding to its situation on the sea-shore. Those who have observed it mantling the rocks of the Mediterranean in winter, with its grey flowers glittering with dew, cannot but be struck with the elegant propriety of the name.—Linn. Gen. 16. Schreb. 22. Willd. Sp. Pl. v. 1. 126. Mart. Mill. Dict. v. 4. Sm. Prodr. Fl. Græc. Sibth. v. 1. 12. Ait. Hort. Kew. v. 1. 52. Tournef. t. 92. Juss. 111. Lamarck Illustr. t. 19.—Class and order, *Diandria Monogynia*. Nat. Ord. *Verticillata*, Linn. *Labiata*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, compressed at the upper part, with an erect mouth; upper lip undivided; lower cloven. *Cor.* unequal; tube longer than the calyx; limb gaping; upper lip divided into two parts, erect, shorter, acute, with reflexed margins; lower reflexed, trifid; the middle segment very large, concave, narrow at the base; the lateral ones narrow, acute. *Stam.* Filaments two, awl-shaped, simple, with a tooth at one side, inclined towards the upper lip, and exceeding it in length; anthers simple. *Pist.* Germen superior, four-cleft; style resembling the stamens; stigma simple, acute. *Peric.* none, except the permanent calyx, which contains four ovate seeds in its bottom.

Obf. This genus approaches very near to *Salvia*, from which however it differs in having the stamens simply furnished with a lateral tooth.

Efl. Ch. Corolla unequal, its upper lip cloven. Filaments longer than the corolla, curved, simple with a tooth. Calyx campanulate, trifid. Seeds four, naked.

1. *R. officinalis*. Common Rosemary. Linn. Sp. Pl. 33. Sm. Fl. Græc. Sibth. t. 14. Woodv. Med. Bot. t. 87.—Leaves sessile.—Native of the south of Europe, the Levant, and occasionally in the Grecian islands; common in gardens, flowering from January to May.—An erect, evergreen shrub, four feet high, very much branched; branches obscurely quadrangular, downy, leafy on all sides. Leaves opposite, spreading in a recurved manner, linear-oblong, obtuse, revolute, entire; smooth, dark green, and shining above; downy and veined beneath. Flowering branches axillary, opposite, short, very leafy. Flowers axillary, terminal, on very short stalks, erect, of a bright blue colour, variegated with purple and white, having, like the leaves, a strong aromatic fragrance, resembling camphor. This is the *Δίαζυμύς*; of Dioscorides and other ancient authors. Rosemary, when wild, has broader leaves, larger flowers, and a stronger scent than when cultivated in our gardens; indeed Miller, following the old writers, regarded this as a sufficient ground to make them distinct species; the former being subject to a variety whose leaves are striped with yellow, and hence called *Gold-striped Rosemary*; the latter varying with a white stripe, and thence named *Silver-striped Rosemary*. The silver variety is very tender. From an old opinion of Rosemary-juice having the property of strengthening the memory, this plant has been poetically made an emblem of remembrance or fidelity; and this was probably the origin of its being worn or used at funerals and weddings.

2. *R. chilensis*. Chili Rosemary. Willd. n. 2. Ait. Hort. Kew. v. 1. 52.—Leaves on stalks.—Native of Chili, and flowering in July. This shrub is only known from Molina's Natural History of Chili, who describes it as having stalked leaves. Future observation must determine whether or not it be really a *Rosmarinus*.

ROSMARINUS, in *Gardening*, contains plants of the hardy, shrubby, evergreen kind, of which the species cultivated is the official rosemary (*R. officinalis*).

There are varieties of this with narrow leaves; with broad leaves; with silver-striped leaves, and with gold-striped leaves.

*Method of Culture*.—In all the sorts it may be effected by planting slips or cuttings in the early spring months, as from March to May, as well as by layers; in performing the first methods of which a quantity of young shoots should be cut, or stripped off, from about five or six to eight or ten inches long, stripping off the lower leaves, and then planting them in a border of light earth, in rows a foot asunder, giving a good watering, and repeating it frequently till they are rooted, which they effect in a short time; in the same year they shoot at top, and become tolerable little plants by autumn; when about the beginning or middle of September, or in the spring following, they may be transplanted where they are designed to remain for growth.

The layers should be laid down in any of the convenient lower young branches, into the earth, in the spring, summer, or autumn, and they will be well rooted by autumn following, when they may be taken off, and planted out where they are to remain for plants.

Almost all the varieties are moderately hardy evergreen plants, though the common green sorts are the most so; the striped kinds being liable to suffer by hard frosts, if much exposed, or planted in wet ground; of course they, as well as all the sorts, should have a warm situation and dry soil: some of the variegated kinds should also be potted, in order to have the shelter of a green-house in winter. They are most durable in dry poor soils. In regard to the uses of these plants, the common green sorts are generally made use of for different medicinal purposes, the leaves as well as the flowers being employed, and both these and the striped kinds are planted out as shrubs for the sake of affording a more full variety. They all afford variety of course in the borders, clumps, and other parts of gardens and shrubberies.

ROSMARINUS, in the *Materia Medica*. See ROSEMARY. ROSMARIUS, in *Zoology*, the name of an animal called also by some the sea-horse, and more usually known by the name of *morfe*.

ROSMITHAL, in *Geography*, a town of Bohemia, in the circle of Prachatitz; 11 miles N. of Blatna.

ROSNAY, a town of France, in the department of the Indre; 8 miles N.E. of Le Blanc.

ROSNY, a town of France, in the department of the Seine and Oise; 3 miles W. of Mantes.—Also, a town of France; 5 miles E. of Paris.

ROSOLIS, or ROS-SOLIS, popularly *Rosa-folis*, *sun-dew*, an agreeable spirituous liquor, formerly much in repute, chiefly taken after meals, by way of a drachm, to aid digestion; being composed of burnt brandy, sugar, cinnamon, and milk-water, and sometimes perfumed with a little musk.

It had its name, because anciently prepared wholly of the distilled water of the plant *Ros folis*, which see; but that plant was at length neglected in the composition.

The best was that of Turin. The French have now a particular kind, not called *ros folis*, but *du roy*; because used with good effect by Louis XIV. It is composed of Spanish wine, in which are infused anise, fennel, aneth, coriander, &c. for three weeks.

ROSOMACHA, or ROSOMAK, in *Zoology*, a name given by the Russians to the glutton. They are, says Olaus, taken by the hunters chiefly on account of their skins,

skins, which are much esteemed by people of fortune for robes, as being variegated with very bright colours, resembling flowers. See *URSUS Gulo*.

**ROSOSZE**, in *Geography*, a town of Austrian Lithuania; 30 miles S.W. of Brzefk.

**ROSOY**. See *ROZOY*.

**ROSPORDEN**, a town of France, in the department of the Finisterre, and chief place of a canton, in the district of Quimper. The place contains 560, and the canton 4413 inhabitants, on a territory of 127½ kilometres, in four communes.

**ROSPUS**, a name used by some authors for the strange fish called the *rana piscatrix*, or frog-fish. See *SEA-devil*.

**ROSS, ALEXANDER**, in *Biography*, was born at Aberdeen, and became master of the grammar-school at Southampton, and chaplain to king Charles I. His works are numerous, of which the best known is "A View of all Religions;" and a curious performance, called "Virgilius Evangelizans," taken wholly from the *Æneid*. He died in 1654, aged 61.

**ROSS, JOHN**, a learned prelate, was born in Herefordshire, and educated at St. John's college, Cambridge, where he took his degree of D.D. in the year 1756. He had some years previously to this published a pamphlet in defence of Dr. Middleton against the criticisms of Dr. Markland, and in 1749 an edition of Cicero's "Epistolæ ad Familiares," in two vols. 8vo. He was presented to the vicarage of Frome, in Somersetshire, and in 1778 he was advanced to the bishopric of Exeter. He died in 1792.

**ROSS, JOHN LOCKHART**, the fifth son of sir James Lockhart, was born in November 1721, and having manifested an inclination for the sea-service, he was, at the age of 14, placed under captain Osborn, who then commanded his majesty's ship the Portland of 50 guns, which sailed in September 1735, for Constantinople. He served in several different ships, and under different commanders, till 1743, when he was advanced to the rank of lieutenant. It was not till 1755 that he was appointed to a command, which was in the *Savage* sloop of war, of 12 guns and 70 men. In a very short time he took a *St. Domingo* merchant-man, valued at 30,000*l.* In the following year he was appointed to the command of the *Tartar* sloop of 24 guns, and 200 men. War was now declared against the French, and on the 20th of September he chased and engaged two French frigates of 28 guns, and drove them into *Morlaix*. Without particularizing the instances of his success, we may observe that, between the 20th of September 1756 and the 19th of October 1758, he took nine privateers, containing 220 guns, and about 2500 men, with the loss of only five men killed and two wounded in the different engagements. At length the name of captain Lockhart was almost sufficient to terrify the enemy to strike. The following fact, which stands upon the most indubitable authority, shews in what manner he was regarded on the seas. A privateer belonging to Bristol, called the *King George*, and commanded by a Mr. Read, having fallen in with an enemy's ship of far superior force, during the night, and finding that the exigencies of her situation demanded the most prompt and vigorous exertions to preserve herself from capture, the commander ran with great spirit along-side, and hailing the enemy, commanded her to strike to the *Tartar*, captain Lockhart, and was instantly obeyed without the smallest hesitation. Captain Lockhart's conduct in protecting the trade of the country was so meritorious, that the magistrates of Plymouth, immediately after his return to port, voted him the freedom of their corporation to be presented him in a gold box. A present equally honourable was made him

the ensuing year, by the merchants and underwriters of London, which consisted of a silver cup and falver, curiously chased, and embossed with his arms, and the representation of the *Tartar*, and the several privateers which had been captured by him.

In 1759 he was promoted to the *Chatham* of 50 guns, and had two smaller vessels put under his command. In a short cruise he took the *Arethusa*, a French frigate of 32 guns. In the following year he was promoted to the *Bedford*, a third rate, but did not long retain the command. In the same year, by the death of a brother, he changed his name to *Rofs*, and was elected a representative in parliament. It was not till 1777 that he was called again to serve his country in the sea-service. In that year he was employed under the orders of admiral Keppel, in the famous battle on the 27th of July. (See *KEPPEL*.) In 1779 he was raised to the rank of rear-admiral of the blue, and appointed fourth in command of the Channel fleet, having hoisted his flag on board the *Royal George* of 100 guns. About this period he succeeded his brother to the dignity of a baronet. He next accompanied sir George Rodney on his fortunate expedition, undertaken for the relief of Gibraltar. After his return he went but little to sea; but in 1787 he was advanced to the rank of vice-admiral of the blue; and here closed the professional career of sir John Lockhart Rofs, who, considering his great zeal and activity in the prosecution of the duties of his profession, and the vast benefits which the commercial interests of his country reaped from his exertions, must be allowed to rank very high in his profession. His coolness and intrepidity in the hour of battle were never surpassed; and, in the course of a very long service, to fight and to conquer were alike habitual to him. He died in June 1790, after a lingering and painful illness; and his remains were interred in the *Rofs* aisle, forming the east end of the church of *Fearn*, which had been the burying-place of all the respectable families of the name of *Rofs* for many ages. Stockdale's edition of *Campbell's Lives of the Admirals*, vol. vi. Charnock's *Biographia Navalis*, vol. vi.

**ROSS**, in *Geography*, a borough and market-town in the lower division of the hundred of *Greytree*, county of *Hereford*, England, is seated on a commanding eminence, overlooking the river *Wye*, at the distance of 15 miles S.E. by E. from the city of *Hereford*, and 121 W. by N. from *London*. This town was made a free borough by king *Henry III.*, and seems to have been a place of more importance formerly than at present. In the time of *Camden* it was famous for its cyder, and for the manufacture of iron wares. Its celebrity for cyder yet continues, but the last-mentioned branch of trade has much declined. According to the parliamentary returns for 1811, *Rofs* contained 558 houses, and a population of 2261 persons. The market-day is *Thursday*, weekly; and the fairs are on *Holy Thursday*, *Corpus Christi*, 20th July, *Thursday* after 10th October, and 11th December. The petty sessions for the hundred of *Greytree* are held here. The government of this borough is vested in a serjeant and four constables, but their powers are extremely limited. Here are two charity schools, and an alms-house; the latter of which owed its establishment to *John Kyrle*, whom *Pope* has characterized and invested with deathless and truly merited fame, by the name of "the Man of *Rofs*." This truly benevolent character was born at *White House*, in the parish of *Dymock*, *Herefordshire*, in 1637; served the office of sheriff for the county in 1683, and died in 1724. Though possessed only of an annual income of 500*l.*, he not only lived in happiness and respectability himself, but diffused around him innumerable

merable benefits to the poor and the unfortunate. Among other advantages conferred by him on Rofs, he raised the church spire above 100 feet in height, and inclosed a piece of ground with a wall, and sunk a reservoir in the centre of it, for the use of the inhabitants. He likewise constructed a fine broad causeway at the western extremity of the town. The house in which Mr. Kyrle resided was afterwards the King's Arms, situated near the entrance of the town from Gloucester, but is no longer an inn.

The streets of Rofs are mostly situated on the top and slope of a hill, and are extremely narrow. The market-house, though erected so late as the reign of Charles II., is in a very decayed state. It is constructed of stone, and displays the heterogeneous mode of building prevalent in the reign of his predecessor, James I. The church is a handsome structure, having a tower, surmounted by a lofty spire at its western end. In the window over the altar here, among other fragments of painted glass, is one representing a bishop, with the inscription, "Thomas Herefordensis," written beneath in black letter. This bishop had probably been a benefactor to the church. The views from the surrounding cemetery, and from the contiguous prospect ground, are much celebrated. Immediately below, the river Wye forms a fine semicircle, at one of the extremities of which are the ruins of Wilton castle; and beyond it an extensive vale, terminated by distant mountains. Near the church-yard is a spot called Bishop's-Court, from the circumstance of its having been anciently the site of a palace, belonging to the bishops of Hereford.

The ruins of Wilton castle above-mentioned stand on the western bank of the Wye. This mansion was for several centuries the residence of the Greys, of the fourth, who derived from it their original baronial title, in the reign of Edward I. soon after they acquired possession of it. Its present ruinous condition is to be attributed to the royalist governors of Hereford, by whose orders the whole interior was consumed by fire. The seats and objects of antiquarian interest in this vicinity are numerous. On the summit of Eaton-hill, about two miles to the north of Rofs, is a large encampment, probably of Roman origin. The intrenchments are in a very perfect state, and are of great depth. A farm-house here displays vestiges of an ancient mansion, and the surrounding grounds are still designated the Park of Eaton; but the history of the place is entirely lost. At a hamlet called Hole-in-the-Wall, about a mile further to the north, are some foundations of walls, which bear the appearance of great antiquity. What occasioned the appellation by which their site is distinguished, is an excavation formed in the rocky bank of a neighbouring garden, which, when complete, led by a flight of steps downwards into a cavity, whose roof was supported by a single column. Ascending the hill towards Old Gore is a hollow space extending about 100 paces, in which a number of celts were discovered a few years ago. These instruments were nearly of the same size, and had evidently been cast, as the marks of the mould were visible. On the opposite side of the river from Hole-in-the-Wall, stands Kingdon-house, long the property of the Hoskyns' family; one of whom, serjeant Hoskyns, is said to have entertained here James I. with a morrice-dance, performed by ten persons whose united ages exceeded one thousand years. Above this mansion is Fawley-Court, anciently the seat of sir John Kyrle, progenitor to the "Man of Rofs," and now the property of a gentleman named Money, a descendant from the family by the female line. Goodrich castle is situated about four miles to the south of Rofs, on a finely wooded promontory, round which

the river Wye forms a semi-circular sweep. This fortress was for many years the baronial residence of the Talbots, earls of Shrewsbury. By whom it was originally founded is unknown, though the near affinity of its name to that of duke Godric, who occurs as a witness to two charters granted by king Canute, renders it not an improbable conjecture that he was the person. Nothing of its authentic history is recorded till the reign of king John, where we find it mentioned as the property of William Strigul, earl marshal, who died here in 1246. Subsequently it was conveyed by a female heir to William de Valentia, earl of Pembroke, from whose family it passed to the Talbots, afterwards earls of Shrewsbury. Elizabeth, daughter of Gilbert, the seventh earl, carried it by marriage to Henry de Grey, earl of Kent, whose descendants held it till the death of Henry, duke of Kent, when it was sold to admiral Griffin, ancestor to the present proprietor. Few events of historical note are related respecting this castle. In the civil wars between king Charles I. and his parliament, it was at first garrisoned for the latter, but was captured soon after by the royalists, who, in their turn, were compelled to surrender it to the republicans, after a siege of six weeks, A.D. 1646. On the 25th of August, in the same year, the parliament ordered it to be notified to the countess of Kent, that it was necessary the castle should be demolished. Accordingly it was dismantled in March following; and has since been gradually falling to decay, but enough of it yet remains to point out its former extent and grandeur. The form of this structure is that of a parallelogram 176 feet long, by 152 broad. Each of the four angles is strengthened by a round tower, and in the south-west part of the area is a square keep, which appears to be of anterior date to the rest of the building. "This keep tower," says King, in his *Munimenta Antiqua*, vol. iii. "has every mark in its style of architecture of being coeval with the Saxon age." It consists of three stories, the lowest of which was used as a prison. The principal entrance was by a flight of steps, which is detached from the main building, and conducts to a platform before the door-way into the second and principal story, which has no interior connection with the dungeon beneath, as happens in most Norman castles. The entrance to the prison-apartments was under a very remarkable fort of pointed arch, formed of "quite flat sides, which seem, from the appearance of the wall around, and from its peculiar style, to have been inserted many ages after the keep was erected, and in the time of Edward III. — a suspicion that appears to be most strongly confirmed by the circumstance, that about the twenty-second year of the reign of that king, Richard Talbot, its then lord, obtained the royal licence for having in his castle a prison for malefactors; having also the cognizance of pleas of the crown, &c. within his lordship of Irehenfield and Wormilow." The windows in the two upper stories are said, by the same author, to be genuine Saxon; and that in the middle of the higher story seems to have continued unaltered from the period of its construction. The columns on each side stand within the arch, the semicircular part of which is ornamented with zigzag: this window terminates the middle projecting buttress that assists in supporting the tower; and under it is a zigzag moulding, or band, which is carried round the whole building. The window in the middle story is nearly similar to that described; but a stone frame for glass is inserted in it, apparently of the age of Henry VI., and probably the work of the celebrated earl Talbot, who, according to tradition, had his private chamber in this keep. The other portions of the castle are of much later erection than the keep. The entrance was very strongly fortified. Immediately in front,

and

and within the space inclosed by the surrounding fosse, was a very deep pit, hewn out of the solid rock, and having a drawbridge thrown across it, which, when drawn up, exactly fitted the space between the towers on each side of the gateway, which was further defended by two massive gates and portcullises, and by loop-holes, and machicolations in the vaulting, through which boiling lead and water were poured down on the heads of assailants. This passage opened into the great inner court, on one side of which stands the chapel, now in ruin; and near it is a small octagonal watch-tower, which rises higher than any other building within the castle. Adjoining the entrance to the keep is the garrison tower, which is thirty-six feet square at the base; "but the three outward angles diminish as they ascend and form triangular buttresses, so that the upper part of the tower is circular." From the keep a wall formerly extended to the west, or Great tower, which is circular in its outward form, but octangular within. Between this and the north, or Ladies' tower, were ranged the late apartments. The hall was a magnificent room, 65 feet long and 28 broad, and appears, from the pointed style of its windows, to have been erected in the reign of Edward I. or II. It communicated, towards the north, with a kind of anti-chamber, whence a passage led into the great state-room; the northern end of which exhibits two most beautiful pointed arches, of a later date than the rest of the apartments. The Ladies' tower occupies a high and steep precipice to the north of this building, and is hence the most defensible part of the castle. Its name clearly indicates its appropriation as the residence of the female part of the garrison. See a plan and views of Goodrich castle, in Bonner's Perspective Itinerary; with historical and descriptive accounts.

Three miles eastward from Rofs is Rofe, or Bury-hill, where some antiquaries have placed the Ariconium of Antoninus, which Camden had fixed erroneously at Kenchester. The site of this station is strongly marked by the colour of the soil, which is extremely black within its area, while all around it is inclined to red. About sixty years ago, the ground here was covered with rubbish, and overgrown with briars, &c. but the then proprietor soon afterwards inclosed and levelled it. In the course of that operation, many Roman antiquities were discovered by the workmen; such as fibulæ, lars, lachrymatories, rings, coins, fragments of pillars, and of tessellated pavements, innumerable pieces of red pottery, and some foundations of buildings. A field near this station retains the name of Kill-Dane-Field, but the particulars of the event to which it alludes is unknown. About a mile to the south-west is the site of Eccleswall castle, now occupied by a modern mansion; and still more to the south, and somewhat nearer to Rofs, are the remains of Penyard castle, which appears to have been constructed for the defence of the narrow pass through the woods from the county of Gloucester, into those of Monmouth and the principality. This fortress was demolished during the civil wars. It had formerly a park and chace attached; and the latter appellation is still given to an eminence which rises to the westward of the castle. Beauties of England and Wales, vol. vi. by E. W. Brayley, and John Britton, 8vo. 1805. King's Munimenta Antiqua, vol. iii. fol.

Ross, a bishopric in Ireland, united with Cork by queen Elizabeth in 1586. It contains 124,000 acres, all in the county of Cork, in 33 parishes.

Ross, a post-town of Ireland, in the county of Cork, distinguished by the name of "Rofs Carbery." It is situated on a bay or harbour, to which it gives its name, but which is cloaked up with sand. The town is situated on a rocky

eminence projecting to the south, and nearly surrounded by a strand. In the centre of the town is a pretty large square, with four narrow streets diverging from its angles. It is chiefly inhabited by weavers, and a good deal of linen yarn is sold here. In former times a school was founded here by St. Fachnan, which was much frequented. It is 155 miles S.W. from Dublin, and 32 from Cork.

Ross, *New*, a sea-port and post-town of Ireland, in the county of Wexford. This, according to Mr. Wakefield, appears to be a spot well adapted for becoming a place of great commercial importance. It is situated at a considerable distance from the coast on the river Barrow, which has a sufficient depth of water to allow vessels of large size to unload at the quay. Not far remote is the junction of this river with the Nore, the latter of which conveys merchandise to Thomastown, within a few miles of Kilkenny, while the former affords a communication by canal to Dublin. The Barrow is also united to the Suire, which is navigable to Clonmell. Notwithstanding these advantages, Mr. W. states Ross to be in a state of inactivity, *without trade or capital*. Other writers speak of it as a flourishing place, the buildings numerous and elegant, and the population rapidly increasing. Ross is a corporate town, and one of the staple ports for the exportation of wool. To the former circumstance Mr. Wakefield attributes its decline. It sends a member to parliament, under the influence of the marquis of Ely. There is a charter school for 60 boys. It is called New Ross, to distinguish it from another, now a mere village, a few miles distant. New Ross is 67½ miles S.S.W. from Dublin.

Ross, a county of the state of Ohio, divided into 11 townships, and containing 15,514 inhabitants.—Also, a town of Washington county, Pennsylvania, containing 1327 inhabitants.

Ross, a small island near the W. coast of Scotland, and county of Argyle; 6 miles N.N.E. of Cambeltown.

Ross-*Island*, lies in the lake of Killarney, county of Kerry, Ireland, in which is a rich vein of grey copper ore, with copper pyrites, galena, and blende, the working of which has been prevented by an influx of the waters of the lake. A castle on this island has a military governor.

Ross's *Island*, a small island in the Mergui Archipelago. N. lat. 10° 44'.

Ross of *Balmangar*, a cape of Scotland, on the S. coast of the county of Kircudbright, at the mouth of the Dee; 4 miles S. of Kircudbright.

POSSA, a small island near the W. coast of the island of Corfica; 10 miles N.E. of Calvi.—Also, a small island in the Mediterranean, near the N. coast of Sardinia. N. lat. 41° 15'. E. long. 9° 25'.

ROSSAL POINT, a cape of England, on the coast of Lancashire; 2 miles W. from the mouth of the river Wyre.

ROSSANO, a city of Naples, in Calabria Citra, the see of an archbishop, formerly the most celebrated rendezvous of Basilian monks in Italy; 27 miles N.N.E. of Cozenza. N. lat. 39° 38'. E. long. 16° 44'.

ROSSARNO, a town of Naples, in Calabria Ultra, on the Metrano; 4 miles S.E. of Nicotera.

ROSSBACH, a town of Saxony, in Thuringia, near which Frederic II. king of Prussia, gained, in the year 1557, a glorious victory over the combined armies of France and Austria; 5 miles N.W. of Weissenfels.

ROSSBACH, *Ober*, a town of Upper Hesse; 2 miles S.W. of Friedberg.

ROSSBACH, *Nider*, a town of Upper Hesse, near Ober Rofsbach.

ROSSCHOCHA, a river of Ruffia, which runs into the Indigirka, N. lat.  $67^{\circ} 50'$ . E. long.  $140^{\circ} 14'$ .

ROSSDEOGHAN, a small island on the W. coast of Ireland, in Kenmare river; 10 miles N.E. of Lamb's Head.

ROSSDORF, a town of Bavaria; 12 miles N.E. of Bamberg.—Also, a town of Germany, in the county of Henneberg; 10 miles N.W. of Meinungen.

ROSSE, in *Ichthyology*, the name given by Bellonius to that kind of cyprinus of Artedi, which we call the roach.

ROSSEL, in *Geography*, a town of Prussia, in the province of Ermeland; 50 miles S.S.E. of Königsberg. N. lat.  $53^{\circ} 57'$ . E. long.  $21^{\circ} 11'$ .

ROSSELAIRE, a town of France, in the department of the Lys; 3 miles N. of Grammont.

ROSSENÄW, a town of Austria; 2 miles N.W. of Zwettl.

ROSSENBURG, a town of the margraviate of Anspach; 8 miles N. of Anspach.

ROSSENDORF, a town of the margraviate of Anspach; 2 miles N.W. of Cadolzburg.

ROSSI, GIAN-VITTORIO, in *Biography*, an Italian man of letters, was born of a good family at Rome, in 1577. He was educated under the Jesuits of the Roman college, where he joined the studies of the law and philosophy to that of polite literature, but being disappointed in his expectations with respect to the first of these pursuits, he limited his attention to the last. He became a member of the academy degli Umoristi, of which he was one of the most zealous promoters, and gave such proofs of ability in its exercises, that several advantageous offers of employment were made to him. He, at length, accepted the post of secretary to the cardinal Andrea Peretti, with whom he resided twenty years. After the death of that prelate he retired to a solitary villa on mount Sant' Onofrio, where he lived in tranquillity to himself, and engaged in his studies, till he died in 1647, at the age of 70. He was much esteemed by the men of letters at Rome, as well as by many persons of rank, among whom was the cardinal Chigi, afterwards pope Alexander VII. Rosli, who is better known by his classical name, Erythreus, was author of several works. His first publication was a kind of satire on the corrupt manners of the Romans, entitled "Eudemizæ Lib. X." He also published two volumes of "Epistles," addressed to cardinal Chigi, under the name of Tyrrenus, and two others to different persons; also various dialogues on moral topics, orations, and other tracts, which are all in the Latin language. His chief work is entitled "Pinnotheca Imaginum illustrium Virorum," being eulogies or biographical accounts of many learned men his contemporaries. Gen Biog.

ROSSI, PASQUALE, called *Pasqualino of Vicenza*, by long practice after the best Venetian and Roman pictures, acquired, without a master, a considerable power of design and colour. Few of his public works remain; one of the best is a St. Gregorio in the dome of Matelica. In galleries we meet with his cabinet pictures, representing conversations, gaming parties, concerts, and similar capricci, highly elaborate, and of Flemish finish.

ROSSI, LEMME, published in 1666, at Perugia, in quarto, a work entitled "Sistema Musico," or Speculative Music, explaining the most celebrated system of the ancients in all the genera. This is one of the clearest and best digested treatises on harmonics that was produced in Italy during the 17th century.

ROSSI, MICHAEL ANGELO, a dilettante or gentleman-performer on the violin, who, in the part of Apollo, in Vol. XXX.

1632, accompanied himself on that instrument in a musical drama at Rome, entitled "Il Ritorno di Angelica nell' Indie," to the great delight of the audience. It appears that Stradella, who fung in his own oratorio of St. John the Baptist at Rome, led the band, and accompanied his own voice on the violin.

ROSSI. See LUIGI.

ROSSI, LA PASQUA, a female singer in the conservatorio of the Incurabili at Venice in 1770, who performed in a motet by Galuppi under his own direction, in a very superior manner. Italian Tour.

ROSSI, FRANCESCO DI PUGLIA, an excellent musical composer of the old school, who produced the following three operas, that were much admired in their day: "Sejano moderno della Tracia," 1636; "La pena degli Occhi," 1688; and "La Corilda, o l'Amor trionfante della Verdetta."

ROSSIGLIONE, ALTO, in *Geography*, a town of the Ligurian republic; 17 miles N.W. of Genoa.

ROSSIGLIONE, *Basso*, a town of the Ligurian republic; 15 miles N.W. of Genoa.

ROSSIGNOL, a considerable lake of Nova Scotia, between Liverpool and Annapolis, said by the Indians to be the main source of the Liverpool and Petit rivers.—Also, a port on the S. coast of Nova Scotia, S.W. of Port de l'Heve.

ROSSIGNOL, in *Ornithology*. See MOTACILLA *Lucinia* and *Phanicurus*.

ROSSINA, in *Geography*, a town of the duchy of Parma; 14 miles S.S.E. of Parma.

ROSSITA, a river of European Turkey, which runs into the Jantra, near Nicop, in Bulgaria.

ROSSITTEN, a town of Prussia, in the province of Samland, on the Kurisch Nerung; 18 miles N. of Königsberg.

ROSSITZ, a town of Bohemia, in the circle of Chrudim; 8 miles N.N.W. of Chrudim.

ROSSLA, a town of Germany, in the principality of Weimar; 6 miles N.E. of Weimar.

ROSSLEBEN, or ROSSEL, a town of Saxony, in Thuringia; 3 miles N.N.E. of Wiehe.

ROSSLYN, *Earl of*, in *Biography*. See WEDDERBURN.

ROSSMORE, in *Geography*, an island in Kenmare river, county of Kerry, Ireland, about 6 miles W. of Kenmare town.

ROSSO, CAPE, a cape on the E. coast of the island of Metelin. N. lat.  $39^{\circ} 18'$ .

ROSSOCKEN, a town of Prussia, in the province of Oberland; 25 miles S.W. of Ortelburg.

ROSSOMAKA, in *Zoology*. See *Ursus Gulo*.

ROSS-SHIRE, a county or district of Scotland, including the small dispersed county of Cromarty, which united, form one sheriffdom, though separated lieutenancies, is situated between  $57^{\circ} 7' 40''$  and  $58^{\circ} 7' 20''$  north latitude. It is one of the largest shires in North Britain, and extends about eighty miles in length, and seventy-eight in breadth. The whole comprehends 3799 British square miles, of which 562 are in the isle of Lewis, and 344 in Cromarty. Ross-shire stretches across the whole of Scotland, from the northern to the western ocean, and has annexed to it, besides the isles of Lewis, Barra, and Rona, the Sulistker-rock, and the Flannan and Shaint isles, which will be found to be noticed under their respective names. It is bounded on the north by the county of Sutherland, on the east by the Moray and Cromarty friths, on the south by the county of Inverness, and on the west by the Atlantic ocean.

According to the population returns of 1811, the united counties contain 13,280 houses, and 60,853 inhabitants.

*Historical Events*.—Ross-shire, in very remote times, constituted part of the Pictish kingdom. At a later period, when the Norwegians obtained possession of the Orkneys, and subdued the neighbouring counties of Caithness and Sutherland, it seems to have shared the usual fate of frontier provinces, and to have belonged alternately to the Norwegians and to the Scotch. According to the Icelandic writers, it made part of the dominions of the earls of Orkney; but in the “*Descriptio Albanie*,” both the counties of Ross and Moray are mentioned as comprehended within Scotland; and other accounts state that part of Ross-shire was possessed by the princes of the Hebrides, or lords of the Isles. The truth probably is, that, favoured by their peninsular situation, the inhabitants of Ross paid little respect to the authority of any of their powerful neighbours. Ross-shire formed a comitatus, or earldom, as early as the 11th century; but of the history of its first earls scarcely any authentic document exists. What is remarkable, however, contrary to the custom in most other feudal possessions, this earldom seems to have descended to heirs female as well as to heirs male. Hugh, one of the earls of Ross, was slain at the battle of Halidon-hill, in 1333. William, his son, succeeded, who appears to have had some claim to the Western isles, as in a variety of charters, yet extant, he is styled earl of Ross, and lord of Skye. This nobleman slew Raynold of the Isles in a fray at Perth; but in endeavouring to establish a right to his possessions by force, he was completely thwarted. William left issue an only daughter, who married Walter Leslie, and thereby gave him a title to the earldom. His son and successor, Alexander, espoused one of the daughters of the regent of Scotland, Robert, duke of Albany, and had by her a daughter, Euphemia, who, while a child, was induced to resign her rights to the regent’s son, who thereby became earl of Ross and Buchan. He did not, however, long enjoy his honours and possessions in quiet, for on the death of Euphemia, as is generally believed by poison, Donald, lord of the Isles, asserted his title to the earldom of Ross, and being received by the inhabitants, not only succeeded in obtaining possession of the district, but extended his dominions as far southwards as the Grampian hills, and transmitted them to his posterity. John, his son and successor, who lived in the middle of the 15th century, was one of the most powerful chieftains of his age. He used the title of an independent prince, made treaties with Edward IV. of England, &c.; and, indeed, the extent of his territories might well justify such conduct, as his sway was acknowledged over at least a fourth part of the whole kingdom of Scotland.

*General Aspect*.—On the eastern coast of Ross-shire, to a short distance from the sea, the country is comparatively flat, and being chiefly inhabited by persons speaking the English language, has been long considered to be part of the lowlands of Scotland. This tract is extremely fertile and well cultivated, and abounds with seats belonging to opulent and respectable proprietors, by whose exertions it has been greatly improved of late years. The climate is more favourable to agricultural pursuits than in most of the northern districts of our island; so likewise is the soil, which, in many parishes, is a deep loam, capable of yielding very large crops of wheat. In short, such are the natural advantages of this narrow tract, that it is considered little inferior to Fifeshire, either in point of soil or climate. Unfortunately, however, the portion of it susceptible of arable culture, though nearly sixty miles in length, rarely exceeds a mile and a half in breadth, except in the parishes

of Nigg and Tarbet. The soils here are, of course, various. In the parishes of Fodderty, Dingwall, Kiltearn, Nigg, and Eastern Fern, a rich deep loam prevails. About Contin, and in the parishes of Alness, Rosekean, and Kilmuir, the soil is light, but sufficiently favourable for general crops. The other portions consist of a constant succession of lofty mountains. The central district, however, may be justly described as a beautiful Highland country, the hills being covered with a profusion of grass, and every where intersected by straths, or valleys, many of them extremely rich and fertile; but on approaching the western coast the general aspect is uninviting. The traveller who climbs a mountain beholds around him a prospect exhibiting a desolate and dreary region, where nothing can be seen but vast rocky mountains, with summits broken, serrated, and springing into various forms. Yet amidst these hills, so dreary to the sight, and producing little but heath, some valleys, at once beautiful and fertile, intervene, which might be cultivated with advantage, did not the climate to which they are subjected deter the inhabitants. During March and April, the weather is commonly friendly to the operations of the husbandman. In the autumnal months rain falls in such quantities, as to lay the ripening corn flat upon the fields, and to swell every trifling stream into a torrent, by which the lands are stripped of their produce, and sand and stones are substituted. The fair days in this district, according to a register kept at Lochalsh, are estimated at 143 in number annually; but in the months of August, September, October, and November, not more than five days in thirty are free from rain. The soils in the valleys, both here and in the middle district, are mostly alluvial, and partake, in general, of those of the nature of the surrounding mountains. At the head of the bay of Applecross the soil is sandy; and on its southern side rests on lime-stone. At Keeshorn it is of the same description, and very fertile. The soil of Terridon is light and gravelly, with the exception of a few patches of moss, which have lately been brought into a state of cultivation. At loch Carron, a great variety of soil may be observed within a very limited space. On the flat spots along the shore the soil is light and stony; on the higher and sloping grounds, a sandy loam; and at the head of the loch it is of a loose clayey consistence.

*Mineralogy*.—The mineral products of these counties are but very little known, because the subterranean contents have hitherto been but little investigated. Coal is indicated in every part of the Black isle, in Cromarty, and throughout all the eastern parts of Ross-shire. Lime-stone is abundant on the western coast, where it is least wanted, and is likewise partially found at Kirkan, and in the eastern district, particularly in the vicinity of Geanies and Cadboll. Copper has been wrought in primary lime-stone near Keeshorn; but the mine is for the present abandoned. In the parish of Kiltearn, small quantities of lead-ore have been discovered; and a vein of the same metal, very rich in silver, appears in the parish of Alness. Here also is a stratum of iron-stone, which is plentiful in most parts of the eastern district. At Pooley yet remain the ruins of a large smelting-furnace, the existence of which shews the manufacture of iron to have been once an important business in that part of the country. Marl has been found in large quantities in the same district, particularly at Culrain, near the sea; and on the west coast, in the parish of Lochalsh, is an immense bank of shell-sand, the right of property in which has been for many years a subject of litigation between Mr. Innes of Lochalsh, and the clergyman of the parish, Mr. Downie, the former contending that it belongs to him as proprietor of the estate of Lochalsh, and the latter, that it lies within

## ROSS-SHIRE.

within sea-mark, and is therefore *inter regalia*. In the parish of Kincardine stands one of the loftiest mountains in Ross-shire, called Carnchuinaig, on which stones have been found perfectly similar to those known by the name of Cairngorums.

Knockirny, another hill on the borders of the same parish, produces excellent marble, both white and coloured. The other loftiest mountains in Ross-shire are, Tulloch-Ard, in the district of Kintail; Ben-Uaish, in the parish of Kiltearn; and Scuilm-a-bharra, in the parish of Kincardine. That of Tulloch-Ard claims particular attention on account of its importance in remote times. "Like the temple of Janus of ancient Rome, it indicated peace or war; for when war commenced, a barrel of burning tar, on the highest peak, was the signal; and in twenty-four hours all the tenants and vassals of Seaforth appeared at the castle of St. Donan, armed *pro aris et focis*. This mountain is the crest of Seaforth's arms."

*Lochs and Rivers.*—The eastern coast of the united counties of Ross and Cromarty is washed by three large arms of the sea, the Dornoch, Cromarty, and Murray friths.

On the western coast there are eight arms of the sea, stretching for many miles up the country. These are, loch Broom, Little loch Broom, loch Greinord, loch Ew, loch Torbidon, loch Carron, loch Daich, and the Gairloch; all of them the usual resort of vast shoals of herrings. Gairloch has likewise been celebrated, during several centuries, for the cod-fishing. One proprietor, only, sends on an average 40,000 fish of this kind to market annually. The principal fresh-water lakes are loch Maree, and loch Tannich, the former about fifteen miles long, and the latter seven; besides which there are above twenty less considerable lakes, and a great number of small ones. These abound with fine trout and pike, and in some are echars. In loch Maree is found that species of trout called the gizzard trout. This loch is adorned with twenty-four small islands, planted with fir-trees, and other kinds of wood. The largest rivers on the western coast are the Ew, the Carron, and the Broom, which fall into the respective lochs of the same names. The first-mentioned of these is frequented by prodigious numbers of salmon, and is perhaps the best angling stream in Britain. Salmon are likewise plentiful in the Carron, and at Ullapool. On the eastern coast the chief rivers are the Conan, the (east) Carron, the Alnefs, and the Oikel. The Conan and Alnefs fall into the Cromarty frith, which also receives several minor streams. The Carron empties itself into the Dornoch frith, as does likewise the Oikel, which forms the boundary between the counties of Ross and Sutherland. The salmon fisheries on all these rivers are very productive. The river Beaulie, which flows into the Murray frith, is the boundary of the county for several miles on the Invernessshire side.

There is a variety of sulphureous and chalybeate springs in Ross-shire. The spring at Strathpeffer, which is sulphureous, is most remarkable, on account of the very great resort of Highlanders and strangers to drink its waters from a belief in their medicinal qualities for the cure of cutaneous disorders, and of barrenness in women.

*State of Property.*—The value of land in these counties, as in most parts of Great Britain, has vastly increased within the last twenty years. Numerous farms, which, at the commencement of that period, were rented at little more than 200*l.* per annum, have been leased since 1805, as high as 800*l.* or 1000*l.*; and their moided price, when they have been brought to market, has held a proportional elevation. Landlords, trusting to ignorant surveyors, when about to let their lands, generally put a value on them, which expe-

rience has woefully shewn to be far beyond their intrinsic worth. Hence distress arose among the farmers, even when food was at its highest pitch, and most of them were consequently compelled to throw up their leases, or to obtain a considerable reduction of rent.

Most of the estates in Ross and Cromarty shires are held directly under the crown, vice the earls and bishops of Ross. The few duties formerly paid to the earls and bishops are now levied for the government; and being payable chiefly in kind, convertible at the fair price of corn, they have become a very heavy burthen on the estates from which they are taken. Until lately almost every extensive proprietor committed the management of his estate to a factor, but the evils of this practice have at length begun to operate a cure. "There can be no doubt," observes sir George Mackenzie, in his "General View of the Agriculture" of these counties, "but that the crowded population of the Highlands, and their consequent slow improvement, must be attributed, in a great measure, to the extensive power given to factors." The late factor of the proprietor of Lochalsh, by his injudicious conduct, involved his employer in numerous litigations with the minister of the parish, and with his tenants, some of which have been depending for upwards of nine years. The principal landholders are the heirs of the late lord Seaforth, Mr. Innes of Lochalsh, sir Hugh Monro of Fowls castle, sir Alexander Munro of Novar house, sir Hector Mackenzie of Conanfide, sir Roderick Mackenzie of Rosehaugh, sir Charles Ross of Balnagown castle, and Alexander Ross, esq. of Cromarty house. This mansion is by far the most elegant, and the best laid out building of any in this part of the united kingdom, but the pleasure-grounds have been much neglected.

*Agriculture.*—The proprietors of the eastern district of these counties are very spirited in improving, and follow every species of good husbandry practised in the south. Farmers of the superior class begin to imitate their example; but the smaller tenants are far behind. The usual grains cultivated on the arable lands are bear, oats, potatoes, pease and beans, and, along the shore, wheat. Every rotation customary in the south has been tried; but the want of markets within the county has induced many to lay their farms down with grass. The grasses generally sown, both for hay and pasturage, are red and white clover, with a mixture of rye-grass and rib-grass. The ordinary rotation practised by the small tenants, and which they have uniformly pursued for centuries, is bear, or bigg, with manure, followed by two crops of oats, or sometimes pease, and always a quantity of potatoes; on which root their families are chiefly maintained during nine months of the year. The gentlemen, and more extensive farmers, use lime, marle, and shelly-sand, as manure. The smaller tenants make a compost at the rate of one load of dung to three of earth, which they deposit for some time in pits, and then spread in February on the stubble land. The manure is then ploughed down, and another ploughing is given towards the end of April, when they sow their bear, or bigg. The shelly-sand on the west coast is reckoned a very valuable manure; it lasts from twelve to fifteen years, and has the effect of converting a light brown insipid soil into rich black loam. The size of farms here is various. The native farmers occupy from seven to thirty-seven acres of arable land; and, in some instances, have small grazings contiguous to their arable fields; but, for the most part, the horses and cattle employed in the labour of the farms are sent, as soon as feed-time is over, to graze during summer on some hill pasture, for which five or six shillings per head are paid. The gentlemen, and better sort of farmers, possess from 300 to 800

## ROSS-SHIRE.

acres, which are in general inclosed; but the rest of the country is almost entirely open field. Among the smaller tenants leases usually run from five to seven years, at the end of which an increase of rent is most frequently demanded. This limitation of leases greatly retards improvement; for the tenant can reap but little benefit from his labour in so short a space of time; and if he has done any thing more than his neighbours, his farm is coveted, and he must either give a greater increase of rent than it can properly bear, or remove. There are some estates, however, in the leasing of which a different practice has been adopted, to the mutual advantage of the landholder and the tenant.

The central and western districts of Ross-shire may be considered as exclusively devoted to pasturage; the small quantities of arable lands in the vallies bearing but a very insignificant proportion to the extent of the country. Till within the last thirty years these districts were inhabited by a number of small farmers who maintained themselves and their families from the produce of the little spots they had to cultivate, and who, in favourable seasons, were enabled to pay the trifling rent imposed by the landlord, from the profit of the cattle they possessed. These extensive districts, particularly the central district, are now converted from cattle into sheep farms; and there is no question of their superior adaptation to the latter species of stock. For every pound of beef which a Highland cattle grazier can send to market, a shepherd can at least bring three pounds of mutton. The wool also furnishes the staple for a useful and important branch of manufacture. Hence the shepherd can afford a double rent with ease; and there can hardly exist a doubt that property in the Highlands will, in process of time, be tripled, or even quadrupled, by sheep farming. The result, however, upon the population of the country is becoming more and more evident. In proportion as capital is acquired, farms augment in magnitude, and a smaller number of people find employment and support within a given space.

*Live-Stock.*—The cattle reared in the low parts of these counties are chiefly intended for the dairy, and are a mixed breed. The oxen and old cows are commonly fattened for the butchers of Inverness and Fort George. The breeds of sheep kept are various. The pure Cheviots, a mixture of that breed with the Leicester, and a mixture of the latter with the old white-faced horned breed of the country, are frequently met with, and also the pure Leicester. Some gentlemen have introduced the South Down and the Merino, and have successfully attempted crosses of these with the Cheviot breed. The mountain breed is not larger than ponies, but by care and attention in breeding, the size and utility might be greatly augmented. The breed of hogs kept by gentlemen for their tables, is that of China; but the country people chiefly rear the large common sow. Turkeys, ducks, pea fowls, Guinea fowls, and common fowls, are reared by most of the families residing in the country, but only to supply their own consumption. Pigeon-houses are very frequent; and bees are beginning to attract considerable attention.

*Roads.*—Through the cultivated parts of the county the roads have been long noted for their excellence, though there were no other means for making or repairing than the ordinary statute labour. About seven years ago, however, a bill for converting the statute labour into money was presented to parliament, and passed into a law. By this act, the post-road from the borders of the county of Ross, near Beauly, to its termination at the Frith of Dornoch, is to be made turnpike; and authority is given for the erection of toll-gates every six miles. The materials for making roads

are every where found in great abundance; but the number of bridges required renders road-making very expensive. The roads forming by government, and the Highland counties conjointly, will cost, on an average, 250*l.* per mile; though their breadth be only fifteen feet. The roads in the mountainous districts, if roads they can be called, are very bad; but most of them are in progress of amelioration. The road from Contin to Lochcarron is considerably advanced.

*Towns and Villages.*—In the united counties of Ross and Cromarty there are three royal boroughs, all of them situated in the eastern district. These are Tain, on the southern side of the Frith of Dornoch; Dingwall, at the inland extremity of the Frith of Cromarty; and Fortrose, on the northern side of the Moray Frith. Of the villages, the most worthy of notice are Cromarty, Ullapool, Fairtoosh, and Lochalsh: the last has lately been constituted a burgh of barony. Fairtoosh is remarkable for the singular privilege it enjoyed for nearly a century, of exemption from excise, on condition of an annual payment of 400 marks Scots. This right was resumed by government in 1786, and the sum of 20,000*l.* was granted as a compensation to the proprietor. Before that period, Fairtoosh whiskey was proverbial for its purity and excellence; and even yet, the appellation of real Fairtoosh is used to denote the best samples of that favourite Highland beverage. Fairs, markets, and “trysts” for cattle, are held at various places throughout the country; some of them established by custom, and others by acts of parliament.

*Manufactures and Commerce.*—The only manufacture which has been established in these counties is that of biscuit and cotton-bagging at Cromarty, with branches at Invergordon and Port-Mahomack. This is carried on to a considerable extent. The bagging made at these places, and at Inverness, obtains a decided preference, under the name of Inverness bagging, where it is principally sold. Many years ago, a flax manufactory was attempted to be established, but without success. With respect to commerce, it may be observed, that the chief exports are black cattle, sheep, and wool, and a considerable quantity of wheat and oats.

*Antiquities.*—Ross-shire contains a considerable number of remains of antiquity, which are not unworthy of notice. These consist chiefly of Druidical temples, and Pictish or Danish forts, called Duns, and of the castles of the ancient chieftains. In the parish of Kiltearn, in the eastern district, is a Druidical temple, consisting of a row of twelve large stones, so disposed as to form two conjoined ovals. The area of each oval is 13 feet long and 10 feet broad in the centre. At the western extremity of one of them is a stone, which rises eight feet above the surface of the ground; but the other stones do not exceed six feet in length. In the middle of the western oval is a flat stone, which was probably the altar; and at the distance of three paces from the eastern oval is a circular hollow, said to have been a well of considerable depth, but it is now filled up. These ovals occupy the summit of an eminence, round which are drawn three concentric circular ditches; and at the distance of half a mile to the westward is a cairn, 30 paces in diameter, containing in the centre a grave 3½ feet long, 18 inches broad, and 1½ deep, lined by four flat stones, and covered by another. Cairns are also numerous on the adjoining hill. In the parish of Nigg, on the the same coast, stands a large obelisk, on one side of which are cut the figures of different animals, and on the other a cross. The former is supposed to be a much older work than the latter; and the tradition is, that the stone was erected in memory of a shipwreck, by which three

three sons of one of the Danish monarchs are said to have lost their lives, and their bodies buried under the obelisk. The rock opposite, where the vessel struck, is from this circumstance still called the King's-Sons. Another obelisk, similar to the above, formerly stood in Nigg church-yard, but the base of it alone remains. Near Dunskeath, on the ledge of a rock over-hanging the Moray frith, are the remains of a castle, built in 1179, by William, surnamed the Lion, king of Scotland. In the parish of Kincardine is Craighenican, where the gallant marquis of Montrose fought his last battle. He swam to Kyle, and lay some time concealed in Assint; but being discovered and apprehended he was sent prisoner to Inverness. The ground where the battle took place received its present name from the event of that memorable day. Near the church, in the same parish, is an alley, walled in, and terminating in a large semicircle, appropriated to the military exercise and discipline, distinguished by the name of Weapon-shawing; and in the cemetery is a stone sculptured with an imperial crown, and a man on horse-back, in the act of darting a lance. Tradition reports it to be the upper part of a stone coffin, in which the remains of a prince of Loellin, who died of his wounds in the neighbourhood, were deposited. In the same neighbourhood are also several Druidical circles, and likewise some of the round buildings which were formerly mentioned under the denomination of Picts-houses. Near Avoch, the foundations still remain of a large old castle, or fortalice. To this ruin tradition gives the name of Douglas castle. It is about 350 feet long and 160 feet broad, divided into numerous apartments, which appear to have been constructed of coarse red quarry-stone and lime; and was defended on one side by a deep fosse, and on another by bastions. Throughout every part of the eastern district are abundance of places where battles with the Danes and Norwegians, or between rival clans, are said to have been fought. Numbers of cairns point out the spots where the ashes of the dead have been deposited, though concerning most of them tradition is silent. In the parish of Eddertoun, however, on a plain to the west of the church, tradition says a great battle was fought against the Danes, one of whose princes, who fell in action, lies buried in the centre of a large circular barrow in the immediate vicinity. In the parish of Fearn are several Druidical temples; but the most interesting monuments of antiquity here are the abbey and castle of Lochlin. The abbey-church was long used for divine service, but is now in a state of ruin. The castle occupies the summit of a very lofty eminence, and is one of the most conspicuous objects in the country. It is built in the form of two squares, joined together at the corners. Another very ancient castle was situated at Cadboll, whence it derived its name. Few remains of it now exist, except the vaults under ground; but it deserves notice on account of a singular tradition concerning it, which is fully credited by the vulgar, *viz.* that though it was inhabited for many centuries, no person ever died in it; in short, that it possessed a magical charm against death, though not against disease, or the evils attendant on extreme old age. Hence many of the inhabitants, it is said, when they became weary of life, requested to be carried out of the castle, that they might obtain relief. The castle of Craighouse, in the parish of Kirk-Michael, stands close to the shore, inclosed on the land side by a ditch and high wall. All the apartments of that portion of the mansion now most entire are vaulted with stone. This castle was long the property of the family of Williamson, who emigrated to Germany; it afterwards became the occasional residence of the bishops of Ross. In this vicinity is a great number of ancient encampments, like-

wife various tumuli and cairns. In Killernan parish are two ancient structures, Killcoy and Redcastle, of considerable strength. The latter was anciently of some importance. It was annexed to the crown in 1455, and was constituted a borough of barony, and a free-port, with the right of holding weekly markets, and levying toll and anchorage dues. Rory Mackenzie, the proprietor of Redcastle in 1646, having joined the rebellious standard of the gallant marquis of Montrose, was taken prisoner near Balveny, in Morayshire, and suffered the death of a traitor. During his absence the castle was garrisoned by his sons and dependants, but was soon after stormed and taken by a party of royalists, who put the garrison to the sword and set fire to the buildings. In the mountainous peninsula of Kintail, on the west coast, stand the ruins of the castle of Donan, which was built by Alexander III. of Scotland, to resist the depredations of the Danes. Colin Fitzgerald, ancestor to the late earl of Seaforth, was made comtable of the castle, for his bravery at the battle of Largs, fought in 1263. In 1715 it was taken from the king's forces by stratagem; but two years afterwards, having been attacked on the sea side, by a line of battle ship, it was demolished. In the front of a clergyman's house, in Kintail, stands Donan-Diarmed, or the fort of Diarmed. It is of a circular form, twenty feet in diameter, and of the same height. Diarmed's tomb is on the north-east side of the fort.

Such parts of Ross-shire as are included in the Hebrides, the reader will find noticed under their respective names, and also under the words WESTERN ISLANDS. Beauties of Scotland, vol. v. Lond. 8vo. 1808. A General View of the Agriculture, &c. of the Counties of Ross and Cromarty, by Sir George Stuart Mackenzie, bart. Lond. 8vo. 1810.

ROST, JOHN CHRISTOPHER, in *Biography*, a German poet, was born at Leipzig in the year 1717. He received a good education, and as he advanced in life he studied, with the utmost assiduity, jurisprudence, antiquities, and the belles lettres. His chief instructor was Ernesti, but he studied philosophy also under Hoffman, and attended the lectures of Gottsched, to whose praise he devoted the first fruits of his muse, though he afterwards wrote against him a satirical poem, which was published in 1743. This is said to be the best of his productions, and to abound with genuine and delicate wit. He attempted pastorals in the German language, which were printed at Berlin in 1742, but the morality of them is exceedingly lax, and vice is exhibited too frequently under the captivating form of innocence. A new edition of them appeared at Dresden in 1744, entitled "An Attempt at Pastoral Poetry, with other poetical Pieces," and a third was published in 1768. In 1746, Rost was appointed secretary and librarian to count Bruhl, and died in 1765, in the 48th year of his age. His miscellaneous poems were published after his death, in 1769. Gen. Biog.

ROST, in *Metallurgy*, a term used by the miners at Chrennitz to express the ore of gold after it has been washed and powdered, and melted first with lime-stone, and afterwards burnt with charcoal alone. See LECII.

ROSTAD, in *Geography*, a town of Norway; 70 miles N. of Drontheim.

ROSTAK, a town of Arabia, in the province of Oman, the seat of a sovereign prince, at some distance from the sea; 70 miles W. of Mascat.

ROSTAR, a town of Persia, in the province of Larissan; 90 miles S. of Mar.

ROSTAL, a town of Germany, in the principality of Anspach; 7 miles N.N.W. of Schwabach.

ROSTAN,

**ROSTAN**, a town of Syria, in the pachalic of Damascus; 45 miles N.N.E. of Damascus.

**ROSTAYN**, a town of Bohemia, in the circle of Boleslau; 4 miles N. of Aycha.

**ROSTEN**, in the *Materia Medica* of earlier ages, a name given to crab's eyes.

**ROSTER**, in *Military Language*, a plan, or table, by which the duty of officers, entire battalions, and squadrons, is regulated.

**ROSTGAARD, FREDERICK**, in *Biography*, a learned Danish writer, was born at Kraagerup, in Seland, in the year 1671. He was educated at Copenhagen, and in 1690 he undertook a tour through Europe; in the course of which he paid a visit to the most celebrated universities of Germany, Holland, England, France, and Italy. After his return in 1669, he was made private keeper of the records to his Danish majesty, and in 1702 was ennobled and appointed a counsellor of justice. In 1721 he became chief secretary in the Danish chancery, and after receiving a considerable pension, he was nominated in 1735 a counsellor of conference. He died in 1745, and bequeathed to the library of the university of Copenhagen a great many manuscripts and several printed books, consisting mostly of historical works, with a large fount of Arabic and Persian types. He was author of a great number of works, among which the following may be enumerated: "Deliciæ Poëtarum Danorum;" "A Danish Translation of Corneille's Cid;" "Projet d'une nouvelle Methodé pour dresser le Catalogue d'une Bibliothèque selon les Matières avec le Plan;" "Enchiridion studiosi, Arabicè cum Versione Latina, edit. ab Hadriano Relando." He collected, with great care, and at a considerable expence, in various parts of France and Italy, manuscripts of "Libanii Epistolæ," from which the edition of J. C. Wolfius of Hamburg was published. It was through the exertions of Rostgaard that the "Fragmentum Theoticum Isidori Hispalensis" was discovered and published in the second volume of the Danish Bibliothecæ. He was the author of many Latin and Danish poems, and was employed for several years on a Danish Lexicon, as well as in collecting rare Arabic and Greek manuscripts, and heraldic documents relating to the Danish nobility. Gen. Biog.

**ROSTOCK**, in *Geography*, a sea-port town of Germany, in the circle of Lower Saxony, and duchy of Mecklenburg, on a lake which communicates with the Baltic. It contains three churches and an university, jointly founded by the dukes and the town in the year 1419, and privileged by a bull of pope Martin V. afterwards confirmed by the emperor Ferdinand I. But in 1437, the town fell under the ban both of the emperor and pope, and the professors removed to Griefswalde, whence they returned again in 1443. In 1487, on account of a misunderstanding between the dukes and the town, the university was removed to Lubeck, but again restored in 1492. The place has thrice suffered from the pestilence, and at the commencement of the reformation was deserted by its professors and students till the year 1530, and in 1560 the emperor Ferdinand afforded it a new charter. In pursuance of a convention made, in 1563, between the dukes and the town, the former nominate and pay fifteen professors, and the town nine. It was also agreed that the dukes should annually contribute 3000 florins, and the town 500, towards the salaries of the professors. The magistracy consists of three burgher-masters, one syndic, twelve aldermen, one secretary, and a prothonotary. It possesses the right of coining copper, silver, and gold, and therefore has a mint. Both the civil and criminal jurisdiction are vested in the magistracy, with right of appeal to the two

supreme courts of justice, except in those cases where no appeal is allowed. The town enjoys other considerable privileges; nevertheless it is hereditarily subject to the dukes, in acknowledgment of which subjection it annually pays 55 rixdollars, as an original tribute, and also 600 florins, for the grant of an excise. The trade of this town is very considerable. In the year 1218 it was admitted into the Hanseatic confederacy; 25 miles N.E. of Weismar. N. lat. 54° 10'. E. long. 12° 12'.

**ROSTOV**, a town of Russia, in the government of Jaroslavl, situated near a lake, to which it gives name: the see of a bishop; 36 miles S. of Jaroslavl. N. lat. 57°. E. long. 39° 54'.

**ROSTRA**, in *Antiquity*, a part of the Roman forum, wherein orations, pleadings, funeral harangues, &c. were delivered.

The rostrum was a kind of chapel, taken out of the forum, and furnished with a suggestum, or eminence, called more particularly the rostra, where the orators stood to speak.

It was adorned, or, as Livy says, built, with the beaks of ships taken from the people of Antium, in a naval engagement; whence the name.

There were two kinds of rostra; *rostra vetera* and *rostra nova*. The latter was erected by Augustus, and decorated with the prows of vessels which he took at the battle of Actium. The first were those already described.

**ROSTRALIS CORONA**, *Rostral Crown*. See CROWN.

**ROSTRALIS Columna**, *Rostral Column*. See COLUMN.

**ROSTRATA**, in *Zoology*. See TOUCAN.

**ROSTRENEN** in *Geography*, a town of France, and principal place of a district, in the department of the North Coasts; 20 miles S. of Guingamp. N. lat. 48° 14'. W. long. 3° 15'.

**ROSTREVOR**, a post-town of the county of Down, Ireland, situate on the bay of Carlingford, and much frequented for sea-bathing. Mr. Wakefield calls it the Brighton of Ireland, and it has been much admired for its romantic scenery. It is a wooded bank, on a small arm of the sea, and has behind it the Mourne mountains. It is 57½ miles N. from Dublin, and 7½ from Newry.

**ROSTRIFORMIS PROCESSUS**, in *Anatomy*, the same as coracoides.

**ROSTRUM** literally denotes the beak or bill of a bird. This is a hard horny substance, consisting of an upper and under part, extending from the head, and answering to the mandibles in quadrupeds. Its edges are generally plain and sharp, like the edge of a knife, or cultrated; sometimes serrated, or jagged, or pectinated, or denticulated; but always destitute of real teeth immersed in sockets. See *Anatomy of BIRDS*.

Hence the word is also figuratively applied to the beak, or fore-part, of the head of a ship.

The rostrum, or snout, in fishes, varies very much in figure, and serves as a considerable article of distinction. It is, 1. In some plagioplateous, or depressed, as in the pike, &c. 2. In some it is conic in shape, as in the oxyrynchus, &c. 3. In some it is extended into a long and sharp point, as in the common ones. And, 4. In others it is triangular, or nearly so, as in the rays. See FISH.

**ROSTRUM** is also used to signify an instrument, with which paper is ruled for musical compositions.

**ROSTRUM**, in *Chemistry*, signifies the nose, or beak, of the common alembic, which conveys the liquor distilled into its receiver.

**ROSTRUM** is also a sort of crooked scissars, which the surgeons,

furgeons, in some cases, make use of for the dilatation of wounds.

**ROSTRUM Leporinum**, in *Surgery*, the piece of flesh situated betwixt the margins of a hare-lip.

**ROSTRUM Seminis**, in *Botany*, the beak of the seed, is an elongation of the apex of a naked seed, originating either in the base of the style itself, remaining in a hardened state (see *DICHROMENA*); or it consists of an appendage to the whole fruit, composed of two naked seeds; as in *Scandix*. The same term applies to a similar elongation of certain seed-vessels; as in *Geranium* and its allies, whose beaks bear a strong analogy to those of *Scandix*; and in *Helleborus*, *Delphinium*, and abundance of other genera, where they originate from the indurated styles.

**ROSWEIDE**, **HERIBERT**, in *Biography*, a learned Dutch Jesuit, and writer in ecclesiastical antiquities, was born at Utrecht in the year 1569. He entered among the disciples of Loyola, at Doway in Flanders, when he was 20 years of age, and soon discovered the subjects of study peculiarly adapted to his genius, by spending the time which he was allowed to devote to exercise and recreation, in examining the libraries of the monasteries in that city, and rescuing the ancient manuscripts contained in them from dust and oblivion. Having completed his course of academical studies, he filled successively the chairs of philosophy and divinity, first at Doway and afterwards at Antwerp, with great reputation for several years. After this he devoted his time to the composition and publication of his various works. He died in 1629, at the age of 60. He published, in 1607, "*Fasti Sanctorum quorum Vitæ in Belgicis Bibliothecis Manuscriptæ asservantur*," which he intended as a specimen of a larger work, and which was the prototype of the immense collection by Bollandus and others, under the title of *Acta Sanctorum*. He was author of many other works, among which is "An Account of the Hermits of Egypt and Palestine," "An Ecclesiastical History from the Time of Christ to Pope Urban VIII." in two vols. folio; and "The History of the Belgic Church."

**ROSWALD**, in *Geography*, a town of Moravia, in the circle of Prerau, insulated in Silesia; 6 miles N. of Jagendorf.

**ROSWICK**, a town of Sweden, in West Bothnia; 10 miles N. of Pitea.

**ROSYCRUSIANS**, **ROSIERUCIANS**, *Rosicrucians*, or *Brothers of the Rosy-cross*, a name assumed by a sect or cabal of hermetical philosophers, or of *Theosophists*; who arose, as it has been said, or at least became first taken notice of, in Germany, in the beginning of the 14th century.

They bound themselves together by a solemn secret, which they all swore inviolably to preserve; and obliged themselves, at their admission into the order, to a strict observance of certain established rules.

They pretended to know all sciences, and chiefly medicine; of which they published themselves the restorers. They pretended to be masters of abundance of important secrets; and, among others, that of the philosopher's stone; all which they have affirmed to have received by tradition from the ancient Egyptians, Chaldeans, the Magi, and Gymnosophists.

Their chief was a German gentleman, called Christian Rosencruz, educated in a monastery, where he learnt the languages. About the close of the 14th century he went to the Holy Land, and visited the holy sepulchre; and falling sick at Damascus, he consulted the Arabs, and other eastern philosophers, by whom he was supposed to be initiated into this wonderful art. At his return into Germany, he formed

a society, to whom he communicated the secrets he had brought with him out of the East, under an inviolable oath of secrecy, and finally died in 1484.

This society remained concealed till the beginning of the 17th century, when two books were published; the one entitled "*Fama Fraternitatis laudabilis Ordinis Rosæcruis*," The Report of the laudable Fraternity of Rosicrucians; the other, "*Confessio Fraternitatis*," The Confession of the Fraternity. In these works the world was informed, that the fraternity was enabled, by divine revelation, to explain the most important secrets both of nature and grace; that they were appointed to correct the errors of the learned world, particularly in philosophy and medicine; that they were possessed of the philosopher's stone, and understood both the art of transmuting metals and of prolonging human life; and in fine, that by their means the golden age would return. As soon as these grand secrets were divulged, the whole tribe of the Paracelsists, Theosophists, and chemists, flocked to the Rosicrucian standard, and every new and unheard-of mystery was referred to this fraternity. Various were the opinions that were formed of this society; but though its laws and statutes had appeared, no one could tell where the society itself was to be found, or who really belonged to it. It was imagined by some sagacious observers, that a certain important meaning was concealed under the story of the Rosicrucian fraternity, though they were wholly unable to say what it was. One conjectured that some chemical mystery lay hid behind the allegorical tale; another supposed that it foretold some great ecclesiastical revolution. At last Michael Brele, in the year 1620, had the courage publicly to declare, that he certainly knew the whole story to have been the contrivance of some ingenious persons, who chose to amuse themselves by imposing upon the public credulity. This declaration raised a suspicion against the whole story; and as no one undertook to contradict it, this wonderful society daily vanished, and the rumours which had been spread concerning it ceased. The whole was probably a contrivance to ridicule the pretenders to secret wisdom and wonderful power, particularly the chemists, who boasted that they possessed the philosopher's stone. It has been conjectured, says Brucker, and the satirical turn of his writings, and several particular passages in his works, favour the conjecture, that this farce was invented and performed, in part at least, by John Valentine Andrea, a divine of Wartenburg.

We shall here subjoin some further particulars concerning the Rosicrucians.

They have been distinguished by several names, accommodated to the several branches of their doctrine.

Because they pretend to protract the period of human life, by means of certain nostrums, and even to restore youth, they were called *immortales*.

As they pretended to know all things, they have been called *illuminati*: and because they have made no appearance for several years, but have kept altogether incognito, they have been called the *invisible brothers*.

Their society is frequently signed by the letters F. R. C., which some among them interpret *fratres rosis cœli*; it being pretended, that the matter of the philosopher's stone is dew concocted, exalted, &c.

Some, who are no friends to free-masonry, make the present flourishing society of free-masons a branch of Rosicrucians; or rather the Rosicrucians themselves, under a new name or relation; *viz.* as retainers to building. And it is certain, there are some free-masons who have all the characters of Rosicrucians; but how the era and original of masonry, as traced by Mr. Anderson, and that of Rosicrucianism,

crucianism, here fixed from Naudæus, who has written expressly on the subject, consist, we leave others to judge.

Notwithstanding the pretended antiquity of the Rosicrucians, it is probable that the alchemists, Paracelsists, or *fire philosophers*, who spread themselves through almost all Europe, about the close of the 16th century, assumed, about this period, the obscure and ambiguous title of Rosicrucian brethren, which commanded, at first, some degree of respect, as it seemed to be borrowed from the arms of Luther, which were a *cross* placed upon a *rose*.

But the denomination evidently appears to be derived from the science of chemistry. It is not compounded, says Mosheim, as many imagine, of the two words *rosa* and *crux*, which signify *rose* and *cross*, but of the latter of these words, and the Latin word *ros*, which signifies *dew*. Of all natural bodies, dew was esteemed the most powerful dissolvent of gold; and the *cross*, in the chemical language, is equivalent to *light*, because the figure of a cross + exhibits, at the same time, the three letters of which the word *lux*, or *light*, is compounded. Now *lux* is called, by this sect, the seed or menstruum of the red dragon, or, in other words, that gross and corporeal light, which, when properly digested and modified, produces gold. Hence it follows, if this etymology be admitted, that a Rosicrucian philosopher is one, who, by the intervention and assistance of the dew, seeks for light, or, in other words, the substance called the philosopher's stone.

The true meaning and energy of this denomination did not escape the penetration and sagacity of Gassendi, as appears by his *Examen Philosophiæ Fluddanæ*, sect. 15. tom. iii. p. 261. And it was more fully explained by Renaudot, in his *Conférences Publiques*, tom. iv. p. 87.

At the head of these fanatics were Robert Fludd, an English physician, Jacob Behmen, and Michael Mayer. The common principles, which serve as a kind of centre of union to the Rosicrucian society, are the following. They all maintain that the dissolution of bodies, by the power of fire, is the only way by which men can arrive at true wisdom, and come to discern the first principles of things. They all acknowledge a certain analogy and harmony between the powers of nature and the doctrines of religion, and believe that the Deity governs the kingdom of grace by the same laws with which he rules the kingdom of nature; and hence they are led to use chemical denominations to express the truths of religion. They all hold, that there is a sort of divine energy, or soul, diffused through the frame of the universe, which some call the *archæus*, others the *universal spirit*, and which others mention under different appellations. They all talk in the most superstitious manner of what they call the signature of things, of the power of the stars over all corporeal beings, and their particular influence upon the human race, of the efficacy of magic, and the various ranks and orders of demons. In fine, they all agree in throwing out the most crude incomprehensible notions and ideas, in the most obscure, quaint, and unusual expressions. Brucker's *Hist. Philos.* by Enfield, vol. ii. Mosh. *Eccl. Hist.* vol. iv. Eng. ed. Svo. See BEHMISTS and THEOSOPHISTS.

ROT, in *Rural Economy*, a sort of putrid decay, taking place gradually in different substances, either from the effects of moisture or other causes. Much mischief is frequently done in this way to different kinds of materials of the farm sort.

This sort of decay in materials, whether of the manure or other kinds, is greatly promoted by their being kept in a continued moist condition, by the atmospheric air being freely admitted to them; and where they are of a strawy, littersy, or light nature, by their being thrown together in

rather an open manner. The contact of the earth or mould also promotes this kind of rot in a very great degree. There is likewise a great variety of other causes, which have a tendency to bring on and expedite the decay of substances both of the hard and less firm kinds. See PUTREFACTION.

ROT, among sheep-farmers, a disease incident to sheep and other animals, in which both the liver and lungs are affected, and there is often a dropical tendency. It is mostly connected with moisture or moist situations; but its causes are far from being perfectly investigated. Dr. Harrison of Lincolnshire has, however, lately done much in this way, and drawn many useful and scientific conclusions. The disease is readily known to experienced shepherds by a careful examination of the eye, which is done by placing the sheep between his thighs, and holding the head with both hands. He then proceeds to raise the upper, and depress the under eye-lid, by which means the blood-vessels of the tunica albuginea, or white, are brought into view. When they are red, and in great numbers, the sheep is supposed to be in good health. The caruncula lacrymalis, or raw and inner surface of the eye-lids, should be as red as the vessels on the eye-ball. If they are pale, and the veins are in small quantities, and faint-coloured, or livid, the sheep is in a debilitated state, or afflicted with the rot. And in all cases where the blood-vessels have entirely disappeared, the mutton is bad. By frequently examining the eyes in dangerous seasons, shepherds may always discover the rot before the sheep begin to shrink, and, consequently, in time to prevent any material injury to their profits.

The above intelligent writer traces the nature and effects of the disease in the following manner: when in warm, sultry, and rainy weather, sheep that are grazing on low and moist lands feed rapidly, and some of them die suddenly, there is reason to fear that they have contracted the rot. This suspicion will be further increased, if in a few weeks afterwards the sheep begin to shrink, and become flaccid in their loins. By pressure about the hips at this time, a crackling is sometimes perceptible. Now, or soon afterwards, the countenance looks pale, and upon parting the fleece, the skin is found to have exchanged its vermilion tint for a pale red; and the wool is easily separated from the pelt. As the disorder advances, the skin becomes dappled with yellow, or black spots. About this time the eyes lose their lustre, and become white and pearly, from the red vessels of the tunica adnata, and eye-lids, being contracted or entirely obliterated. To this succeed debility and emaciation, which increase continually till the sheep die; or else ascites, and perhaps general dropsy supervene, before the fatal termination. These symptoms are rendered more severe by an obstinate purging, which comes on at an uncertain period of the disorder. In the progress of the complaint, sheep become what the graziers call *choked*, that is, affected with a swelling under the chin, which proceeds from a fluid contained in the cellular membrane, under the throat. And he adds, that in five or six days after contracting the rot, the thin edge of the small lobe of the liver becomes of a transparent white, or blueish colour, and this spreads along the upper and lower sides, according to the severity of the complaint. Sometimes it does not extend more than an inch from the margin. In severe cases, the whole peritoneum investing the liver is diseased; and then it commonly assumes an opaque colour, interspersed with dark red lines or patches. The upper part of the liver is sometimes speckled like the body of a toad, to which it is said to bear a striking resemblance; round the ductus communis cholecocus and hepatic vessels, a jelly-like matter is deposited, which

which varies according to the severity of the attack, from a table-spoonful, or less, to five or six times that quantity. Upon boiling, the liver loses its firmness, and separates into small pieces in the water, or remains soft and flaccid. And it is observed, that graziers and butchers having remarked that sheep are much disposed to feed during the first three or four weeks after being tainted, avail themselves of this circumstance very commonly to increase their profits. When the first stage is over, flukes begin to appear in the *pori biliarii*, the *ductus communis choledocus*, and in the gall-bladder. At first the number of these creatures is small; but as the disease advances they increase, and before death, are often very numerous. In the last part of the complaint, they are sometimes to be found in the stomach as well as in the intestines and liver. This, like the visceral disorders of the human body, may terminate in resolution, effusion, suppuration, or schirrus. 1st. The complaint is said to terminate in resolution, when the inflammatory action goes off, without destroying the state and texture of the parts. However, he is strongly inclined to believe, that every considerable inflammation in the human body, and in other animals, although it ends in resolution, leaves behind it some remains, which may be discovered by an experienced anatomist. When the vessels are thrown into inflammatory action for a few days only, effusion commonly takes place, and the coats become thicker, and assume a buff-like colour. These changes in the sanguinary system often continue through life, and lay the foundation of many chronic and incurable disorders. Sheep that recover from the rot exhibit very different appearances after death, according to the severity of the attack; but the taint is seldom or never entirely removed. The liver of an old ewe, that lately died fat, and contained fourteen pounds of fuet in her body, had the following appearances: the back part of the small lobe was dappled with whitish spots; the coats of the *ductus communis* and *pori biliarii* were considerably thickened, and more solid than usual. In colour they resembled the human aorta in old people, and were full of flukes: in other respects the liver appeared to be found and natural. The butcher asserted that the variegated appearance and alteration in the ducts were occasioned by a slight taint of long standing, which had not been considerable enough to disorder the economy, or impair the health of the animal sufficiently to prevent its feeding.

2dly. That when sheep die suddenly in the first stage of the disorder, an effusion of serum, or of wheyish-coloured fluid, may be commonly discovered in the cavity of the abdomen, and then the peritoneum surrounding the liver is generally covered with a membrane or coat of coagulable lymph. This form of the rot has been frequently confounded with the resp or red water, though it differs from the latter disorder in the colour of the effused liquid, in being much less exposed to putrefaction, and in several other particulars.

3dly. And that abscesses in the liver exhibit another termination of this malady. They are seldom considerable enough to kill immediately; but, in consequence of the absorption of purulent matter from them, the sheep frequently waste away, and die hectic or dropical. When the collections are small, sheep will recover sufficiently to bear lambs, for three or four seasons, and afterwards become tolerable mutton. 4thly. That the most common termination is in schirri, or what the shepherds call knots in the liver. The whole substance of this important viscus has been found so full of small roundish lumps, or schirrous bodies, that it was difficult to find any found part in it. The first attack is unfortunately so very insidious, that the disorder is scarcely

observable before the animal begins to waste and lose flesh. In this advanced state it is said to labour under the rot or pourriture, from overlooking the commencement of the disorder. And hydatids are observed to effect schirrous and purulent livers more frequently than others. When livers are much diseased, the butchers carefully conceal them from the public eye. To him it is always matter of surprize to find the mutton saleable in these severe cases. It shews, in an extraordinary manner, the accommodating power of living matter, which is able to maintain life, and increase corpulence, under such unfavourable circumstances. Shepherds and breeders, who make it a general rule to kill every sheep that becomes indisposed, from an opinion that very few of them ever recover from any illness, would do well to examine the livers and other viscera of slaughtered sheep. By such a practice they would soon be convinced that sheep are able to endure a great deal.

But in respect to the causes of the disease, it has been imputed, 1st, to a vitiated dew; 2dly, to a crust, which adheres to grass after wet weather, or the overflowing of running water; 3dly, to the luxuriant and quick growth of plants, in hot, moist seasons; 4thly, to grazing certain herbs; 5thly, to *fasciolæ hepaticæ*, or their ova, being introduced into the stomachs of animals, by feeding on swampy and low grounds in moist weather; 6thly, it has been called the *sheep-poxx* by professor Vibourg, of the veterinary college at Copenhagen; but this is not properly the cause of the rot. And, 7thly, it is ascribed, by Daubenton, to poor diet, and drinking too much water. These different causes are objected to, and shewn not well founded by the first writer, who thinks that, 8thly, it seems to be occasioned by poisonous effluvia, which, under certain circumstances, are emitted from marshy soils, in support of which it is stated that the following facts afford strong proofs.

His residence consists of high and low lands, of a loamy and tenacious nature. While a brook which runs through the farm remains overflowed, and the water continues upon the adjoining flat grounds, his sheep never suffer any inconvenience, though they are frequently obliged to wade for their provisions. As soon as the flood is subsided, the sheep can at any time be tainted in a quarter of an hour, while the land retains its moisture, and the weather is hot and sultry. The butchers are so well acquainted with the importance of this fact, that when his friend has disposed of any fat sheep, they are usually turned upon this rotten ground to make them thrive faster. But by judicious management he has laid the greatest part of his farm completely dry, and is now little troubled with the rot, unless when he wishes to give it to some particular animals. His neighbours, who have been less provident, are still severe sufferers by it; nor are their misfortunes confined to sheep alone. Pigs, cows, asses, horses, poultry, hares and rabbits, become rotten in this lordship, and have flukes in their livers. Many years since, his grandfather removed ninety sheep from a considerable distance to his own residence. On coming near to a bridge, which is thrown over the Barling's river, one of the drove fell into a ditch, and fractured its fore-leg. The shepherd immediately took it in his arms to a neighbouring house, and replaced the limb. During this time, which did not occupy more than one hour, the remainder were left to graze in the ditches and lanes. The flock were then driven home, and in a month afterwards, the other sheep joined its companions. The shepherd soon discovered that all had contracted the rot except the lame sheep; and as they were never separated upon any other occasion, it is reasonable to conclude that the disorder was acquired by feeding in the

road and ditch bottoms. And he adds, that a Lincolnshire farmer purchased some turnips in Nottinghamshire, upon which he intended to winter a flock of sheep. The first division, consisting of about forty, were detained one night at a village near to the place formerly alluded to, by the overflowing of the Barling's Ean, and were put upon a piece of flat land which leads to the river. The water had not returned to its former channel more than a day or two. Every one of the forty sheep became rotten; whereas the other division, which stopped no where by the way, escaped the disorder, and remained well. Sheep were formerly admitted into some adjoining pastures, in travelling to and from the neighbouring fairs and markets; but so many of them contracted the rot, that, for some time past, the graziers in this county will not suffer their flocks to stop for a moment near the village. He has repeatedly examined the suspected ditches and pastures, but never observed either flukes, or any of the plants, to which the rot has been attributed: though he must candidly acknowledge that he ought to have sought for them with more care and attention. These ditches communicate with a rivulet, which frequently overflows its banks, and the inclosures are then deluged with water. The soil consists chiefly of loam or clay, and the surface is so flat and level on both sides of the river, that for want of proper descent, the water is a long time detained upon the grounds. He is credibly informed, that in this place the rot affects swine, hares, and rabbits, as well as sheep.

It is further stated, that he has likewise been informed by Mr. David Wright, that a few years since, as a drove of sheep were passing through a long lane in the parish of Irby, one of them, being weary, fell down in the middle of the road. The others were permitted to range at large, till their companion was able to travel. They were then driven all together into a pasture, and it was soon discovered that only the *tired* sheep had escaped the rot. As the flock had never been separated upon any occasion, we are entitled to conclude that the disorder was contracted while the tired animal remained upon the road. From these and other cases, the writer thinks himself justified in ascribing the rot in sheep, and other animals, to *paludal* effluvia; but in regard to the nature and constitution of which he acknowledges it is very difficult to form any rational opinion, as they have hitherto eluded the most subtle and delicate inquiries.

In respect to the prevention of the disorder, he suggests, that where necessity requires the pasturage of moist grounds in summer or autumn, the shepherd ought carefully to remove his flock into a dry situation before the evening, and provide them with corn, and good hay, or green food. He says that a considerable farmer of Bohemia kept his sheep found in the wet and fatal year of 1769, by feeding them every night, when turned under a shed, or into stables, with hatched straw; and by eating it greedily they were all saved. By this judicious practice, the sheep were removed to sleep in better air, as well as preserved in a more vigorous state of body. Sir John Pringle informs us, that persons have maintained themselves in good health, during fiekly seasons, by inhabiting the upper stories of their houses; and he has reason to believe, that by merely confining sheep on high grounds through the night, they have escaped the rot. He adds, that after the dew is exhale by the sun's heat, sheep may be suffered to range in moist and swampy places, with less danger, because the miasmata, which are formed in the night, and remain entangled among the grass, or float in the lower part of the atmosphere, are chiefly dissipated with the dew. Therefore, unless they be very copiously produced in the day time, or are unusually virulent, they

will not be sufficiently concentrated to do much injury to healthy sheep. While at rest and asleep, the operations of the system are more feebly performed, and then sheep are peculiarly exposed to diseased actions. By conforming to these regulations, he has known one flock escape entirely, while others have suffered materially in the same open field.

And it is confidently asserted, that decoctions of bitter herbs, with salt, have frequently preserved sheep from the rot. Salt is supposed to constitute a part of Fleet's celebrated nostrum; and we know that bitters are deservedly recommended to prevent intermittents, the dysentery, and other disorders, which originate from exhalations. In Oxfordshire, Dr. Lower has frequently known six or seven spoonsful of strong brine and stale urine, with foot steeped in it, to be given with great success. This is done at spring and the fall of the year, when the dew is counted most dangerous. This course of physic is continued eight or ten days, or till the sheep eat their meat heartily; and if they were taken in time, there seldom died any in a whole flock. For the same purpose, Ellis recommends the following medicine in his "Practical Husbandry." Take a peck or more of malt, and mash it, as though you would brew it into ale or beer, and make eleven or twelve gallons of liquor; then boil in it a quantity of shepherd's purse, comfrey, sage, plantain, penny-royal, wormwood, and blood-wort: add yeast, and afterwards salt the mixture; then turn the liquor into a vessel. After April comes in, give seven or eight spoonsful to every sheep, once in the week, if the weather be wet, and if dry not so often.

Some have supposed that there are various objections to the above notions concerning the nature and causes of the rot in sheep; but especially that of its not being met with in the sheep of some other districts where *marsh miasmata*, and the diseases which depend upon it, greatly prevail. It has, indeed, been stated in the view of eliciting the truth of the matter, by Dr. George Pearson, that there is an apparent difficulty or objection to the above writer's conclusion—that the rot in these animals is occasioned by the same morbid agent which occasions intermittent and remittent fevers—in the circumstance that in some of the marshes of the county of Kent, where intermittent fevers affect a great proportion of the inhabitants; and even persons residing in the neighbourhood, although living on dry chalky lands, where such diseases never shew themselves, if at some distance from the low grounds, unless in consequence of importation; and in Chitney marsh, on the river Medway, near the isle of Sheppey, one of the most prolific situations for agues to be found in the kingdom; and which is equally famous for its pasturage, by which very great numbers of sheep are fed and kept; where the fallow and indeed cadaverous countenances of the inhabitants, shewed that most of them were ill, or were recovering from agues; on inquiring into the health of the sheep, besides the evidence of the fine healthy condition of the animals, it was found, on the authority of a shepherd who had lived thirty-six years in the marsh, that he had only seen the disorder once, and that was in the first year of his residence there; nor is the rot at all common in any part of the county of Kent. The Leicester breed of sheep, he asserted, were subject to it, but not the sheep bred in the marsh; nor were these animals subject to any other disease more frequently than in other situations in general, or particularly in the uplands. On these grounds, the doctor thinks, it would appear that one kind of miasmata of marshes which produce agues, do not in all situations also produce the rot. He does not, however, conceive it logically just to conclude, from the instance which has been

given, that miasmata paludum of a different species may not occasion the rot, and also agues. It is possible also, he supposes, that some concomitant agents or circumstances may render the same miasmata productive of one of the diseases in certain situations, but not of the other disorder.

The same circumstances occur in other situations, as there is a prevalence of miasmata in the Romney Marsh, another great sheep district, which frequently produces intermittent and remittent fevers; while the rot is scarcely ever known to happen in it. And in Essex there are agues in plenty, in many parts, without the rot in the sheep of them being at all known.

Some of these remarks and directions deserve the notice of the grazing farmer, as by proper attention to them much mischief may often be prevented. But there are some who suppose that most dependence in the cure of this affection is to be placed upon the removal of sheep into dry situations, keeping them warm and sheltered, and giving them dry food in the yard. In the Report on Agriculture for Lincolnshire, some circumstances are given that may direct the farmer on this point. It is stated, that in rotting years, the sheep that feed on the salt marshes over which the spring-tides come, fell very high in confidence that they are safe. And that a shepherd, who when young was shepherd's boy to an old man who lived at Netlam, a place noted for the rot, says he is persuaded that sheep only take the rot in a morning before the dew is off, as by keeping them up till the dew is gone they have been preserved from the disease, while others, where this precaution has been neglected, have become disordered.

Others think that the best and surest remedy, in these cases, is that of combining plenty of dry food with the free use of sea-salt, and at the same time removing the animals to the sound, rich, dry, pasture lands. The rot is never known to be caught on the South Downs of Suffex. When the sheep suffer in this way, the disease is always got while they are keeping in the weald, or other low lands. Such marshes as are occasionally overflowed by salt-water, are never known to rot sheep, but are most admirable for keeping them sound and healthy; and should any thing be capable of curing the rot, it is the sheep feeding on such land. Some have observed, that if, after a frost, even when very early, sheep be turned into such meadows and brooks as are at other times particularly liable to rot them, they will not, under this circumstance, suffer at all; as it is supposed the animalcule which the insects deposit in the summer among the herbage, are destroyed by the frost. The flounders found in the livers of the animals, are believed to be taken up with their food. It is more probable, however, that it is only the very minute ova of such insects which are taken into the stomachs of such sheep. The autumnal months, when there is no frost, are the most disposed to bring on the rot in the above district; but after one single night of hard frost, the danger is over for that year.

Rotten sheep have, in a great many instances, been cured by feeding them on the herbage growing on a thin soil on lime-stone rock. Hundreds have been known to have become sound on lime-stone land; their livers being completely healed, and the sheep healthy in every respect.

In the original Agricultural Report of the county of Stafford, it is suggested, that the rot in sheep may be removed by the use of medicine. The disease is conceived as perhaps rather similar in its nature to the dropsy, as there is a preternatural abundance of water. The writer remarks, that of six rotten sheep which he had about six years before the time of writing, he succeeded in curing five of them, but the sixth died full of water. One of the five which

were cured brought him a lamb the following year, which with its mother, continued healthy, and became fat on grass; the lamb was sold in the summer, and the ewe in the beginning of winter, to a butcher. The other four also fattened, but in less time, on grass alone, and were parted with in the like manner. On April the 25th, in the year 1802, he also drenched two rotten ewes, one of them in the last stage of the disease; they both became sound, acquired fat, and were sold, with many others, in October, to the butcher, undistinguished from the rest. Since that time he has repeatedly tried the same remedy; and on the whole number of cases, has not lost more than one in six or seven.

His method of performing the cure is this: the rotten sheep is to be fasted one night, then one table spoonful of the spirits of turpentine is to be taken, and mixed with two of the same spoonful of soft cold water; which is to be given to each sheep for one dose. The sheep is then to be kept on dry food for three or four days; at the end of which time, the same dose of the medicine is again to be repeated, and the sheep continued on dry food for three days longer; at the conclusion of which period such sheep may be permitted to join the flock. When affected with a considerable degree of looseness, sheep have often been cured in this manner with great facility.

In short, it may be concluded, in regard to the cure of this disease, which seems to be caused by a general debility or weakness of the whole system, accompanied with a local affection of the same nature in the liver, that all such foods and remedies as are of a dry nourishing quality, and which excite and strengthen the constitution, will constantly be found of great utility, if not wholly capable of affording a perfect cure of the disease.

The following receipt was presented to the Royal Society, by Mr. Boyle, and is preserved in their register, vol. ii. p. 303. Some time before Allhollantide, the sheep is to be blooded under the eye, and, if necessary, again in the spring; and, in October, his gums may be rubbed at three or four different times with Spanish salt. But the principal remedy consists in this: that about Allhollantide, or somewhat sooner, you take a small handful of the fore-mentioned salt, and making the sheep hold up his head, compel him to swallow it, and keep him from drinking any thing for about an hour after.

Rot, *Dry*, in *Rural Economy*, a highly destructive vegetable disease, affecting the timber in the foundations, and other parts of buildings, in particular soils and situations. It affects the wood, or ligneous parts, in such a manner as to leave it connected by nothing but the small hard fibrous portions, which give it a curious tremulous appearance, but all of which, when touched by the hand in the more advanced stages of the disease, readily moulder into a brownish snuff-like dust. It is attended with a peculiar earthy smell, similar to that which issues from fresh dug up wood, which has lain some time in the ground in contact with decaying animal matter. It is very materially different from that natural sort of decay which takes place in wood from the presence of wetness. This has been supposed to originate from very different causes, such as the use of wood in too green a state, excessive dampness in the foundations of the buildings which are affected with it, the want of a free circulation of air in such situations, and more lately to be the effect of a plant of the fungus tribe, which has leaves as in the milletoe, &c. the boletus lachrymans. And on the former suppositions it has been stated to the Society for the Encouragement of Arts, &c. by Mr. Bramley of Leeds, in the thirty-first volume of their Transactions, that to bring the matter to the test by experiments, would require the observations of a

long period, and in selected situations. And that wood used for the general purposes of man is cut down at different periods; and although it may be felled at the proper season, or when most free from sap or moisture, it is not always to be effected. Nay, even admitting it to have been cut down in the most favourable situation, it still abounds with such an extra proportion of moisture, as to require a regular exposure to the air prior to its being applied to use, if we wish to guard against that shrinking which always takes place where this precaution has not been taken. And although the fir kind contains less of this watery portion, yet it assuredly possesses a considerable share; and it is in this species, he apprehends, that the evil called the dry rot most generally occurs, as from the facility of working the same it is most generally applied in buildings. But supposing it to be fir, or any other species, wood felled when abounding with any extra proportion of sap, and applied to use without the proper seasoning or exposure to a free current of air, until such extra moisture has had time to exhale, is most liable to the disease in question; and the cure, or principal prevention against it, would be the precaution of felling all wood only at the proper season, or when the sap is not in circulation. The next mode of prevention would be to use such wood only as has been for a considerable period exposed to the influence of a free current of air, or, where convenience will admit, to that of air heated to a moderate degree; such air extracting with greater facility the enclosed moisture, and in a more certain ratio than the irregularity of our atmosphere will allow, under other circumstances.

And it is suggested, that in all rapidly-improving countries, this evil is likely to be an increasing one, as the current demand for wood generally exceeds the supplies laid by in store, so as to be applied to use in regular succession, after being properly seasoned. And that another cause that affects all wood most materially, when not fully dried, is the application of paint, the nature of which prevents all exhalation, and confines the enclosed moisture, till it occasions a fermentation through the whole fibrous system of the wood, and brings on a premature state of decomposition, or the dry rot. It is likewise supposed that a similar evil may be induced, in consequence of any newly finished building having all the doors and windows shut up, and that for some length of time, particularly in moist weather. The wood, even though unpainted, is thus frequently placed in our atmosphere more charged with vapour than in its own internal contents, and it is consequently in an imbibing instead of an exhaling state, and tending to decay. Wood placed in dampish situations, and the ends of timbers near to moist walls, suffer from similar causes, but what particularly attracted his observation to the circumstances was this, that both oak and fir posts were brought into this premature state of decay, from their having been painted prior to the due evaporation of their moisture; and then extending the observation, and tracing the history of other wood affected in a similar manner, he is convinced that the evil frequently thus originates, and its prevention would be in using timber previously well dried and seasoned for such purposes.

And it is added, that since these observations were made, having been busily engaged in draining from 4000 to 5000 acres of ground, further ideas on the subject of the dry rot have occurred to him from the work he has been engaged in. Where houses are troubled with damp walls, near to the earth's surface, it is generally, if not universally, occasioned by the percolation of water from the higher adjoining ground, which, thus intercepted in its current, attempts to follow the general hydrostatic law, of elevating itself, by

the syphon line, to a height equal to that from whence it has its origin. Thus in houses differently situated, we see the damp arising to varying degrees of height on the walls, and those are probably corresponding to the height at which the moisture circulates in the adjoining ground. At its first entrance to the building, and whilst the moisture is in small quantity, the excavated part of the foundation wall, he thinks, may absorb, and gradually quit such proportion: but the excess, as is generally the case in moist weather, exceeding that power, the foundation stones are then saturated in a more rapid proportion than the adjoining rarefied internal atmosphere can evaporate: the watery particles then creep up, in degrees proportionate to the ascent from which they originally descended, excepting when prevented, or driven off by the superior heat of the adjoining rooms, when, in addition to the disagreeable damp they cause, they frequently occasion considerable damage to the pictures, furniture, &c. Drains laid out athwart the ascending ground, with a very slight descent or fall, and made of the depth of one yard for each yard of ascent, and from the foundation until equal the height that such damp ever rises, would, there is little doubt, completely secure the house and furniture from the inconveniences hitherto sustained, and would generally prove an effectual prevention to most cases of the dry rot, where it originates in extreme moisture. He is of opinion that the fungus which pervades decaying wood is not the first cause, but a dependent on the peculiar state to which such wood has been reduced by prior causes. The disseminated seeds finding a proper bed, or nidus, like to the mushroom, toadstool, &c. fix their abode, and pervade the whole substance, thus accelerating the general law of Providence, which tends to make all matter reproductive.

Upon these grounds cellars, or such other places, should be drained in the manner he has mentioned, by taking off the percolating water prior to its gaining admission to or contact with the walls: and it is probable that, in most cases, a single drain will have complete effect; it would assuredly, he thinks, do so, if it was not for the variation of the earth's internal strata, which are not easily discernible. And that if attention to this rule was paid prior to the building any new streets in towns, it would prove essentially useful in preventing such mischief.

And it has also been suggested to the above society, that mortar made of lime from burnt chalk is much more destructive to timber than stone-lime, or that burnt from lime-stone. Chalk-lime attracts moisture; and communicating it to any timber which it touches, occasions its decay. And further, likewise, that sea-sand is prejudicial, if made into mortar, from a similar quality of attracting moisture from the atmosphere: this, it is supposed, may in some degree be corrected by washing the sand well in fresh water, where good sand cannot be procured. But that good mortar, where any is required to be in contact with timber, may be made from a mixture of stone-lime fresh burnt, and river-sand, to which a very small quantity of common brown, or yellow iron ochre should be added, and well incorporated therewith in the operation of making it up. See QUICKLIME.

And it has been suggested by Mr. Johnson of Ipswich, in the same volume of the Transactions of the above society, that some time between 1771 and 1773, he went, at the request of a friend, to the chapel at the Lock hospital, through curiosity, to examine a pew there that had frequently been repaired for damages by the dry rot. And that after a close investigation, he found it was the operation of a plant, whose leaf resembled that of the vine. Wherever it had touched, the effect of its poisonous quality got through the wood to the paint, which he has seen a mere skin. He proposed to

cover the floor with bricks, laid in mortar, which was accordingly done. He called twice since, the last time about seven years ago, and has reason to think that it never appeared again. That the next opportunity of examining it carefully was at Mark-hall, in Essex, the seat of Mr. Montague Burgoyne. In a parlour there were three pillars of about ten inches in diameter, the outwood of which was between two and three inches thick. Two of them were eaten through in less than seven years, from the bases, about two feet upward, within the hollow, and were as rotten as if it had been the effect of a hundred years standing. The gardener of this gentleman was a botanist; and found the plant where he directed him to search for it, and said it was the *boletus lachrymans*. And, he adds, that some authors call it a parasitical plant; and it is sometimes to be found with the willow and fallow tribe; but this is not to the purpose. Till within a few months he has never been without some leaves of the plant. For many years they appear exhausted and dead, and soon crumble into dust; but he suspects that fresh wood attracts a fresh growth from the root.

At another time, he saw it in a house at Whitehall, built by Sir John Vanbrugh, whose nephew then lived in it. The house is, he thinks, only two stories high; the plant had ascended to the upper story, committing devastation on the wainscot all the way. It will destroy half-inch deal wainscotting in a year. He has also had it twice in houses he inhabited, one in Suffolk, and the other in Gloucestershire. He bore with the first; in the other case he undertook to stop it, and did it effectually.

It is supposed, that the cause is from the floor being laid on the earth, which has been, where he has observed it, of a gravelly or sandy loam nature. The moisture from a water-course at hand, or a north aspect, where the outer wall stands in a garden-bed, so that the rain percolates, are great encouragers; it requires moisture, he suspects. But it never rises in the middle of the floor; because, if the seed were there, it could not germinate for want of air; but it is easy to suppose that after the floor is shrunk, an air may be created between that and the vacancy between the wainscot and the outer wall, sufficient for the purposes of vegetation. He says, he saw an instance last summer in the house of a friend, a student in botany. He was surprised when he told him it was a visit from a plant; but so it proved, and always is, and ever was so; nor does it originate from any other cause.

With the view of removing it in his own case, he removed the original soil near the part affected, and supplied its place with sand. He then placed pieces of tile; on those he laid mortar, and tiles over them, pushing them under the wainscot, so that it had no communication with the joists or floor. Pillars in like manner should, he thinks, be kept from the earth. And in laying a floor upon the ground, he should take away the earth for a foot in breadth, and four inches in depth, all round the walls, and place the ends of the joists in mortar, covering them with tiles pressed under the floor and wainscot, quite to the outward wall. Iron or tin plates would do; but are not so cheap as mortar and tiles, and probably much less durable in such situations. It is supposed that this plant has no adhesive powers, but in contact with wood. If it could pass over brick and mortar, it might be seen to spring from the cellars and infect half the houses in the kingdom. He recommends, in short, that the wainscot be kept free from contact with the joists and floor.

It is observed that the leaves of the plant appearing exhausted and dead, is owing to their having imparted all their

juices to the wood, which change it to a fungus, and not to a powder, like rottenness from length of time. And that nothing is more easy than to prevent the damage from the plant. Besides what he has said above, he is positive that a tile laid close along the walls round the room, would prevent the growth of the plant, even without mortar; and perhaps it is only necessary where the walls are next to the air. And charring the ends of the joists for a few inches, and the side of the wainscot at bottom next the wall, would, he supposes, be sufficient; for the plant cannot adhere to any thing but wood, and that possessed of its natural juices, to a certain degree; so that he questions if old dry oak would receive it. But all the white soft woods, as beech, poplars, and deals, are for a long time ready to receive it. Repairing the damage with fresh wood, without removing the earth and plant, is only feeding the evil, or extending the disease. It is supposed, that as the plant is of the creeping kind, and cannot rise two inches, the wood, in all cases, must be in contact with the earth to support it. He adds, that a fungus broader than the palm of one's hand, and an inch or more in thickness, is commonly seen at the bottom of an old post, on the surface of the earth; but it is not easy to discern whether the wood or the earth furnishes the matter.

The writer further remarks, that he had lately a conversation with an old friend, who shewed him two parcels of rotten wood, from an oak barn-floor laid about sixteen years ago. After lying twelve years, it shook upon the joists. On examination it was found to be rotted in various parts, and the planks, two inches and a half in thickness, were nearly eaten through, though the outside was glossy, and without blemish. The joists, and a large middle beam, were laid at the ends, in brick and mortar, to create a firm level. No earth was near the wood; and, he thinks, that no air could find a passage. The rottenness was partly an impalpable powder, of the colour of Spanish snuff, and other parts were black, as if burnt; the rest was clearly a fungus. And that this gentleman is a person of undoubted veracity; but a nice and exact observation is necessary in such examinations. He thought nothing of any plant, and it is likely there was none of the *boletus*; so that his assertion that it was always to be found, was rather too systematic. He asked him if the timber was dry when laid down. He could not however say that had been particularly adverted to. It had been sawed from a large oak, and was, as he thought, in all respects proper for a barn-floor. As this seems not the operation of the *boletus*, he asks, how did it happen? We know that the oak, when in vegetation, is subject to what we shall call an exudation of juices, which produces the fungus, named the *agaric* of the oak, with which the Druids of old played many tricks. The oak, then, if sawed into thick quantities, may emit these same juices, as the progressive course of nature to its entire decay. It is added that we have all seen oaks of vast size and ancient record, with a great part of the outside whole, and all the inside gone; perhaps the work of a century. In all hollow trees fungus is discoverable. To use a law term, it is a misnomer to call it dry rot; for the rotting principle is in moisture. He further states, that he had never seen the rot upon so large a scale in timber, till lately. The prevention then of beams, rafters, large joists, and posts put into the earth, from decay by the rot, is by charring only, which will dry up all the fungus juices of wood in large substance. Paint, or a bituminous preparation, may probably stop up the pores, and prevent the rot in slight work, where the treatment he before observed, with fire, might be incom-

incommodious, as to half-inch wainscot, &c. The incorruptibility of charcoal is proved by a variety of indisputable facts.

A great many useful facts on this subject have been stated by Mr. Batson, of Limehouse, in the twelfth volume of the same Transactions, in respect to his methods of preventing the dry rot in a room much affected with it. The mode he adopted was to clear the ends of his timbers, to take away the infected earth to the depth of two feet, and to fill up that space with anchor-smith's ashes, or ashes from a foundry, before his flooring boards were laid.

And on minute examinations being made under the direction of the society, at the distances of six and twelve years after the flooring was laid, the boards, wainscot, and timbers, were all found entirely free from any appearance of the dry rot. The use of stone-work next the ground, as the foundations of posts, door frames, partitions, &c. has also been found useful in preventing such wood-works from being attacked by this disease. And also the causing a more free circulation of air about such foundations by the fixing of iron gratings in stone-work in different places, so as to produce the most perfect ventilation. But notwithstanding all that has yet been done in respect to the nature and modes of preventing this sort of rot, much still remains to be effected both in regard to the nature of its origin, and the most certain means of eradicating it under different circumstances.

It will probably, however, be found the best and most effectual plan, until further trials and discoveries have thrown more full and complete light on its nature and causes, to take care that the wood-works near the ground in all buildings in such places as rot timber have as little contact with it as possible, by being raised and supported at some distance from it, by means of solid stone or brick and mortar work, by a full and free circulation of air being every where admitted in the foundations near such wood-works, by being careful to make use of such timber only as is perfectly well seasoned and prepared, and by having constantly a sufficient number of drains made all round to discharge any moisture that may occur. It may likewise be of farther advantage in all such cases to avoid painting or coating over the wood-work near the parts which are liable to be diseased or become rotten, for some considerable length of time after they have been done; as well as to allow of large fires to be occasionally made, where convenient, as near to such situations as possible, in order that every sort of moisture and dampness, together with the peculiar rawness of such new works, may always be removed as much as they are capable of in the first instance, or as soon after the works have been finished as may be compatible with their nature and extent.

In regard to the *boletus lachrymans* being the cause of the dry rot in timber, it has lately been contended that the different sorts of fungus, which are met with upon decaying timber of different kinds, are the production of the remaining powers of life in the sap of the unseasoned wood; and that the same sort of living organizable matter, which, whilst its powers continued in their perfect condition, would have generated the branch of an oak, will, when debilitated and enfeebled, give existence to a certain kind of fungus, and become the cause of this disease.

Mr. T. Wade, in a recent publication, observes, that the term dry rot seems to be improperly applied to the decay in timber, which it is generally employed to designate, and that the impropriety of the expression, probably, has not a little contributed to involve this subject in obscurity. A very short advance in the investigation of this subject will shew,

that moisture is a condition necessary to the putrefactive process, and that water is the most efficient agent in the decomposition of organized bodies.

By capillary attraction fluids are carried to the tops of the highest trees, a phenomenon which has been long observed, but has not been satisfactorily explained. Precisely the same effect takes place when one end of a piece of timber is immersed in water, or placed in a damp situation. It happens even in vacuo.

Timber, so placed, at first swells, after some time it changes colour, then it emits gases which have a mouldy or musty smell. In the more advanced period of decay, the mass dries, and cracks in transverse directions. Lastly, it becomes pulverulent, and forms vegetable mould. Generally, in some of these stages of decomposition, the different species of fungus are found to vegetate on the moss.

When a vegetable is deprived of life, the matter constituting it begins to undergo changes in order to enter into new combinations. It is reduced to simple principles by the aid of warmth, and the presence of air and water. In houses, ships, &c. we cannot prevent the influence of these powerful agents, but it may be retarded. It seems the usual mode of seasoning timber by exsiccation is of little use. Timber, thus prepared, is found, indeed, to shrink and lose much of its weight; but even very old oak timber, (procured from ancient buildings,) when immersed in water, or exposed in a damp situation, readily acquires the weight, and swells to the dimensions of green timber, from which, in its properties, it does not materially differ.

Mr. Wade therefore endeavoured to discover some other means by which timber may be made to resist change, or decay.

*Lignum vita*, box, ebony, &c. are nearly indestructible, owing to their being of so close a texture that water cannot be absorbed by them, neither do they give out any soluble matter to water, at least not without long boiling, or digesting at a very high temperature. Therefore the great agent that determines the changes in wood in general, here has not any influence.

Other durable woods, such as teak, cedar, &c. though of an open grain, and very porous, contain resinous, or oleaginous matter, repelling moisture, which cannot infiltrate itself, as is the case with the feathers of some fowls, &c. On these principles the common perishable woods may be made to resemble those which are very lasting, or, indeed, nearly indestructible.

Thus, to prevent the decay of oak, &c. it is necessary either to cause it to be incapable of absorbing moisture, or to render the ligneous fibre insoluble.

Some of the effects produced bear considerable analogy with tanning, by which process a skin, entirely soluble in water, forming jelly or glue, and quickly susceptible of putrefaction, is made into leather, a substance not at all soluble in water, and capable of enduring for a long period, sometimes for several centuries.

For various methods of performing this, we beg to refer the reader to Mr. Wade's book, in which the operations recommended seem simple and economical.

*Rot in Timber*, a disease in trees which quickly injures and destroys the woody parts of them by inducing a sort of rotting and decay. It has been stated to proceed from different causes, but the principal, according to the author of the *Practical Planter*, are those of external wounds or bruises, the trees growing in unfavourable soils, the roots of which have been barked at the period of planting, or in cutting out plants. And secondly, by the tree growing in  
spouty

spongy foil, whose larger roots have been injudiciously hacked at the time of transplanting, or in cutting out a neighbouring plant. In this case the disease affects the pith, eats upward, and often consumes the heart to such a degree, while the bark remains in a perfectly sound state, that the trunk is enfeebled, and easily broken. This is demonstrated by cutting affected trees at different ages, and the *rot* is generally found less or more advanced upward, according to the size of the cavity. He here states a very curious instance of this species of rot, that occurred at Wemyss castle, in Scotland, in 1795. In thinning a wood, whose trees consisted chiefly of elm and ash, in one part of it the foil was observed to be spongy, and the elm-trees in rather a sickly condition. Every elm-tree cut in this part was more or less affected; some were rotted a foot, others two, three, &c. feet upwards, and the wood above, to the extremity of the bole, was uniformly sound, and sold at two shillings a foot. One beautiful alth-tree, in particular, was sold standing, at the rate of half a crown a foot of timber; nor was there the smallest outward blemish from the ground to the very top. When it was cut down, a completely ready made pump, fifteen feet in length from the ground upwards, was discovered, and actually, as he was afterwards informed, applied as such. It is conceived that in this case the remedy is to be at all due pains to prevent the cause, by carefully draining the soil of poisonous, ochry water, and when necessity occasions the cutting of large roots, to treat them in the manner of an amputated branch.

And a third cause of the rot which he notices, is that of stagnant water lodging in the angle formed by the stem and an upright branch, or in the angle formed by rival stems, where no actual ground has ever been made; but, which often happens, if the tree be in a youthful vigorous state, a cup or hollow is formed, resembling that between the thumb and finger half opened. Here the water lodging, in time penetrates the bark, and forms the first receptacle of corruption, which being once begun advances apace to the great injury of the trees. In this case the first thing necessary towards a cure, or prevention of further injury, is to clean out the water, (for which a syringe may be useful,) dust, &c. and dry the whole well by aid of a mop or woollen cloth; then to fill it up, until it run over, with tar; after which to fix on an apron of thin lead, in such a manner as that its edges may reach about a foot upwards on each limb of the tree, being joined close, and fastened with saddle tacks, &c.

The composition advised by Mr. Forsyth is probably much better for the purpose, as being less liable to decomposition; and at the same time capable of being applied with greater exactness. It is remarked by the first writer that knots or excrescences are frequently found on the boles and branches of trees, particularly of elms. What may have occasioned them, in many cases, is not easily accounted for; but it is sometimes obvious that they proceed from bruises, or the mal-treatment of trees in youth. In this case we frequently find them hollow within, and full of water, which, if not removed, will of a certainty induce the rot. And he advises that when the knot is quite entire on all sides, and perfectly sound, which may be known by striking it with a mallet, it should be suffered to remain. But that when it is found hollow, as above, it should be sawn clean off, the wound should be smoothed, as already directed, cleaned, dried, and laid over with tar, &c. The composition before-mentioned is, however, here probably preferable for the same reason as in that case. See *Composition for TREES, and TIMBER-Trees.*

In cases where the internal parts of trees of the timber

kind become rotten, and get hollow, in consequence of the above, or other causes, as not unfrequently happens to the oak and elm, as well as different other kinds, especially when they are of some considerable length of growth, it has been directed, in order to restore them, that the decayed and rotten wood should be cut out at different times, as the new wood comes in contact with it; great care being taken not to cut too much at any one time, but to leave enough to support the trees, and prevent them from being blown down by high winds, until the new wood is strong enough for that purpose: the remainder may then be cut out, as there will be no danger. By these means, the application of his composition, and heading down, it has been asserted by the late Mr. Forsyth, that a great number of rotten hollow trees, which had, when taken in hand, little more than the bark remaining sound, have within a few years been entirely filled up; and others, that were headed down within a few feet of the ground, have had their stumps completely covered by the leading shoots, forming handsome trees; the places at which they were headed being only discerned by faint cicatrices.

It is stated that a lime-tree, about 18 inches in diameter, whose trunk was decayed, rotten, and hollow, from the top to the bottom, and to which, after cutting out the decayed wood, the composition had been applied about 16 years before, was lately cut down for the purpose of ascertaining the progress it had made in the interior part, and was found entirely filled up with new sound wood, which had completely incorporated with what little old wood remained, when it was first taken in hand. Its body has been cut into short lengths, in order to be shewn, for the sake of convincing those who may be doubtful on the subject.

Also an old elm, the inside of which was totally decayed, and out of which were taken, at different times, two large cart-loads of rotten wood, has made shoots more than 20 feet high in the course of six years. Several others of different sorts are likewise stated to have made equally fine shoots in this mode of treating them, and are now fine thriving trees; the marks of the places at which they were headed down being scarcely perceivable. A lime, the hollow part of which is 11 feet in height, is now, it is said, filling up: the tree is about a foot in diameter. A decayed part, 4 feet long and 28 inches broad, in a large elm, is now, too, stated to be rapidly filling up with sound wood. About two feet and a half in length on one side, which was for some time left to nature, still continued, it is said, to decay, till the composition was applied: new wood and bark are now asserted to be forming in the part. Besides these, a great many other trees of the same kind, some of which had wounds ten feet long and two feet broad, are now also said to be entirely filled up, as well as many fycamores, oaks, and other forest-trees, restored to a flourishing state by having the dead wood cut out, and the composition applied.

However, notwithstanding these and many other similar statements, a variety of doubts and objections have been raised and entertained against this mode of filling up and curing the decayed and rotten parts of forest-trees, by persons of much information and experience on the subject of vegetable economy; so that additional facts, and more careful and exact conclusions from them, are probably necessary before the utility or inutility of the method can be fairly appreciated or fully ascertained.

*ROT in Hops*, a disease in this sort of crops, which is very similar to that of the mould. See *HOP* and *MOULD*.

*ROT, in Geography*, a river of Wurtemberg, which runs into the Lein.

ROTA, a town of Spain, in the province of Seville, on the coast of the Atlantic, celebrated for its wine; 3 miles W. of Puerto de Santa Maria.

ROTA. See ZARPANA.

ROTA, in *Mechanics*. See WHEEL.

ROTA *Aristotelica*, *Aristotle's Wheel*, is the name of a celebrated problem in mechanics, founded on the motion of a wheel about its axis; thus called, because first, that we know of, taken notice of by Aristotle.

The difficulty is this. While a circle makes a revolution on its centre, advancing at the same time in a right line along a plane, it describes, on that plane, a right line, equal to its circumference. Now if this circle, which we may call the *deferent*, carry with it another smaller circle, concentric with it, and which has no motion but what it receives from the deferent; which is the case of the nave of a coach-wheel carried along by the wheel; this little circle, or nave, will describe a line in the time of the revolution, equal, not to its own circumference, but to that of the wheel: because its centre advances in a right line as fast as that of the wheel does; as being in reality the same with it.

The matter of fact is certain; but how it should be, seems a mystery. It is obvious that the wheel, advancing during the revolution, must describe a right line equal to its circumference; but how would the nave, which revolves like the wheel, describe a right line so much greater than its circumference?

The solution Aristotle gives is no more than a good explication of the difficulty. Galileo, who next attempted it, has recourse to an infinity of infinitely little vacuities in the right line described by the two circles; and imagines that the little circle never applies its circumference to those vacuities; but in reality only applies it to a line equal to its own circumference; though it appears to have applied it to a much larger.

But it is evident, that this is all gratis dictum. The vacuities are imaginary; and why does not the great circle apply its circumference to them? Lastly, the magnitude of these vacuities must be augmented or diminished, according to the different proportion of the two circles.

F. Tacquet will have it, that the little circle, making its rotation more slowly than the great one, does on that account describe a line longer than its circumference; yet without applying any point of its circumference to more than one point of its base. But this is no more allowable than the former.

The attempts of so many great men proving vain, M. Dortous de Meyran, a French gentleman, had the good fortune to hit on a solution, which he sent to the Royal Academy of Sciences; where being examined by Messrs. de Louville and Saulmon, appointed for that purpose, they made their report, that it was satisfactory. The solution is to this effect:

The wheel of a coach is only acted on, or drawn in a right line; its circular motion or rotation arises purely from the resistance of the ground on which it is applied.

Now this resistance is equal to the force with which the wheel is drawn in the right line, inasmuch as it defeats that direction; of consequence, the causes of the two motions, the one right, the other circular, are equal; and, therefore, their effects, *i. e.* the motions, are equal. And hence the wheel describes a right line on the ground equal to its circumference.

As for the nave of the wheel, the case is otherwise. It is drawn in a right line by the same force as the wheel; but

it only turns round because the wheel turns, and can only turn with it, and at the same time therewith.

Hence it follows, that its circular velocity is less than that of the wheel in the ratio of the two circumferences; and, therefore, its circular motion is less than its rectilinear one.

Since then it necessarily describes a right line equal to that of the wheel, it can only do it by sliding, or what they call the motion of rotation; that is, a part of the circular nave cannot be applied to a part of a right line greater than itself but by sliding along that part, and that more or less, as the part of the nave is less than that of the circle. See ROTATION.

ROTA is also used for a particular court of jurisdiction in Rome, established for taking cognizance of beneficiary matters, &c.

The rota consists of twelve doctors chosen out of the four nations of Italy, France, Spain, and Germany; three of them being Romans, one a Florentine, one a Milanese, one of Bologna, one of Ferrara, one a Venetian, one a Frenchman, two Spaniards, and one a German; each having four clerks or notaries under him.

Their office is to judge of all beneficiary causes, both within Rome, and throughout the state of the church, in case of appeal, and of all civil processes which are for above five hundred crowns.

They are also called *chaplains* of the pope, as succeeding the ancient judges of the sacred palace, who held their court in his chapel.

The denomination *rota*, *wheel*, some will have derived hence, that they officiate by rotation; others, because the most important affairs of the Christian world turn upon them. Du-Cange derives it from *rota porphyretica*, because the pavement of the chamber where they formerly sat was of porphyry, and fashioned like a wheel.

ROTA, LA, in *Biography*, an admirable bravura singer in the Incurabili Conservatorio at Venice, in 1770, under the regency of Galuppi.

ROTAB, in *Geography*, a river of Saxony, which runs into the Saale, three miles S. of Lena.

ROTACEÆ, in *Botany*, the 20th natural order among the *Fragmenta* of Linnæus, named from *rota*, a wheel, in allusion to the form of the *corolla*, which is wheel-shaped, *rotata*. No commentary upon this order is found in the lectures of Linnæus, published by Giseke. The genera stand thus; *Trientalis*, *Centunculus*, *Anagallis*, *Lysimachia*, *Phlox*, *Exacum*, *Chlora*, *Gentiana*, *Sweritia*, *Chironia*, and *Sarothra*. To which are subjoined, in a separate section, *Ajcyrum*, *Hypericum*, and *Cistus*; these surely have little affinity to the rest.

ROTACH, in *Geography*, a river of Bavaria, which runs into the Maine, near Lichtenfels, in the bishopric of Bamberg.

ROTAI, or ROTTE, a small island in the East Indian sea, where a Dutch factor resides, who trades with the natives in the chief article of their produce, which is sugar. The north end of this island, and the south end of *Timor* (which see), lie N.  $\frac{1}{2}$  E. and S.  $\frac{1}{2}$  W., and are about three or four leagues distant from each other. At the west end of the passage between Rotte and *Semau* (which see), are two small islands, one of which lies near the Rotte shore, and the other off the south-west point of *Semau*, with a good channel between them, about six miles broad. The isle of Rotte has not so lofty and mountainous an appearance as *Timor*, though it is agreeably diversified by hill and valley. On the north side are many sandy beaches, near which grow some trees of the fan palm; but the far greater part was covered

covered with a kind of brushwood without leaves. Cook's Voyage by Hawkesworth, vol. iii. p. 264.

ROTALA, in *Botany*, so named by Linnæus, from *rota*, a wheel; apparently in allusion to the spoke-like appearance of its numerous radiating whorled leaves.—Linn. Mant. 2. 143. Schreb. 33. Willd. Sp. Pl. v. 1. 189. Vahl. Enum. v. 2. 26. Mart. Mill. Dict. v. 4. Juss. 303.—Class and order, *Triandria Monogynia*. Nat. Ord. *Caryophyllei*, sect. 3. Linn. *Caryophylleis affinc*, Jull.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, tubular, membranous, three-toothed, permanent. *Cor.* none. *Stam.* Filaments three, capillary, the length of the calyx; anthers roundish. *Pistl.* Germen superior, ovate; style thread-shaped; stigma three-cleft. *Peric.* Capsule ovate, obscurely triangular, inclosed in the calyx, of three cells, and three valves. *Seeds* numerous, roundish.

Ess. Ch. Calyx three-toothed. Corolla none. Capsule of three cells, with many seeds.

1. *R. verticillaris*. Linn. Mant. 2. 175. (Encycl. pæd.; Rheede Malab. v. 9. 159. t. 81.)—Native of wet situations in the East Indies, from whence it was sent by Koenig to Linnæus. A small annual herb, quite smooth, four inches, or more, in height, erect, branched, having the aspect of an *Ammannia*, as Vahl, from the inspection of the only known specimen, in the Linnæan herbarium, remarked. *Root* with many rows of whorled fibres. *Stem* and *branches* reddish; quadrangular in the upper part. *Leaves* from four, or five, to eight in each whorl, sessile, linear, entire, bluntish, or somewhat emarginate, at the end, about half an inch long; paler, with a prominent rib, beneath. *Flowers* axillary, small, sessile, solitary, pale; their permanent calyx membranous and pellucid, globular, investing the fruit, about the size of a mustard seed.

ROTAS, in *Geography*, a town of Hindoostan, in Lahore, 81½ miles N.W. by N. from Lahore. N. lat. 32° 58'.

ROTAS, a circar of Hindoostan, in the soubah of Bahar, bounded on the N.E. by Boujapour, on the E. by Bahar Proper, on the S. by Palamow, on the W. by the circar of Bidzigur, on the N.W. by Chunar; its form approaching to a square about 58 miles each way. The chief towns are Rotasgur and Saferam. ♀

ROTASGUR, a town of Hindoostan, in the above-mentioned circar, situated on the river Soane; 94 miles S.W. of Patna. N. lat. 24° 38'. E. long. 84° 2'.

ROTATA, COROLLA, in *Botany*, a monopetalous corolla, whose tube is as short as possible, and the limb horizontally extended, like the form of a wheel. This differs from a salver-shaped corolla, in the want of an elongated tube. See COROLLA.

ROTATION, in *Mechanics*, is a term used to denote the motion of the several parts of a solid body about an axis, called the axis of rotation, and which may be either fixed or spontaneous, according as the body is constrained to make its revolution about a determinate point or line, or is free to revolve in any direction from a momentum impressed upon it in space.

We have already treated of several cases of rotatory motion, under our articles CENTER of Gyration, PERCUSSION, OSCILLATION, &c. and it therefore only remains, in this place; to offer some general remarks with regard to such motion, and to enumerate a few of the most important particulars relating to this interesting branch of mechanics.

When a solid body turns round an axis, retaining its shape and dimensions unaltered, every particle is absolutely describing a circle round this axis; which axis passes

through the centre of the circle, and is perpendicular to its plane. Moreover, in any instant of its motion, the particle is moving at right angles with the radius vector, or line joining it with the centre of rotation: therefore, in order to ascertain the direction of the particle, we may draw a line from that particle perpendicular to the axis of rotation. This line will be in the plane of the circle of rotation of that particle, and will be its radius vector; and a line drawn from the particle, perpendicular to its radius vector, will be a tangent to the circle of rotation, and will represent the direction of the motion of this particle.

The whole body being supposed to turn together, it is evident, that when it has made one complete rotation, each point has described the circumference of a circle, and the entire paths of the different particles will be in the proportion of these circumferences, and therefore of their radii: and this is also true of any portion of these circumferences; that is, the velocities of the different particles are proportional to their radii vectores, or to their distances from the axis of rotation; and all these motions are in parallel planes, to which the axis of rotation is perpendicular. Hence it follows, that when we compare the motion of different revolving bodies with respect to velocity, it is evident that it cannot be done by directly comparing the velocity of any particle in one of these bodies with that of any particle of the other; for as all the particles of each have different velocities, this comparison can establish no ratio. But we may familiarly compare such motions, by the number of complete turns which they make in any equal portions of time; and, therefore, as the length or number of feet described by any body, in rectilinear motion, is a proper measure of its progressive velocity, so the angle described by any particle of a revolving body is a proper measure of its motion or rotation: and in this manner may the motion of two or more bodies be compared, and this velocity is with propriety called the angular velocity.

Again, with respect to the motion of bodies at liberty to move freely by the action of any force impressed: if any such body receives an impulsion in any direction, which does not pass through the centre of gravity, the motion which ensues is a rotatory one. For if, at the same moment, a body is impelled according to any direction AB, (*Plate XXXVII. Mechanics, fig. 9.*) not passing through the centre of gravity, an equal and opposite force is exerted upon the body in a parallel direction, CG passing through the centre of gravity, that centre will manifestly be kept at rest: nevertheless it is clear, that the other parts of the body will not be in a state of quiescence, because the two forces, though equal, are not directly opposite; so that the only motion that the body can have, its centre of gravity being at rest, is evidently a motion of rotation about that centre. Now the fixed axis, about which the body revolves, is pressed by the impelling force, while it generates rotatory motion; but the axis, being by hypothesis immoveable, reacts equally against that pressure; and, when it passes through the centre of gravity, would, as above stated, cause each particle to move with the same velocity, and in the direction of the force. If, then, the force which presses against a fixed axis, in given circumstances, be ascertained, the motion of the body in free space, when the axis is removed, will be known; for the latter motion will consist of the rotatory motion about the axis passing through the centre of gravity, considered as fixed, compounded with the motion of the centre of gravity caused by the force now at liberty to impel the centre, the fixed axis which passes through it being removed.

When a solid body receives an impulse on any one point,

## ROTATION.

or that point is urged in any way by a moving force, it cannot move unless the other points, with which it is connected by the force of cohesion, move also; except the force of impulsion is sufficient to overcome that of cohesion, a case which is not meant to be considered here. And whatever is the motion of any particle, that particle must be conceived as urged by a force precisely competent to the production of that motion, by acting immediately on the particle itself. The particle, immediately impelled by the external force, is either pressed towards its neighbouring particles, or is drawn from them; and by this endeavour to change its place, the connecting forces are exerted, or brought into action. We are but little acquainted with these connecting forces; but this is of little importance in a mechanical point of view; for the fact, that the forces by which the molecules of bodies act on each other are equal, is quite sufficient for our present purpose.

After these general remarks, let us endeavour to illustrate the principles above laid down in the solution of a few of the most obvious and most practical cases relating to this important branch of dynamics.

Let A F G H (*Plate XXXVII. Mechanics, fig. 1.*) represent the circumference of a wheel, which turns in its own plane round a horizontal axis, passing through S, its centre; and let a weight P, fixed at the extremity of a line A P, communicate motion to the wheel. Let also the whole weight of the wheel be Q, and suppose this weight to be collected uniformly into the circumference A F G H: then during the descent of the weight P, each point of the circumference must move with a velocity equal to that with which P descends; and consequently since the moving force is the weight P, and the mass moved P + Q, the force which accelerates P in its descent will be that part of the accelerating force of gravity which is expressed by the fraction

$\frac{P}{P + Q}$ . The velocity, therefore, that is generated in P,

in any given time, is found by means of the general formula, given under the article *ACCELERATED Motion*; that is,

$v = 2ft$ ,  $v = \frac{2Pgt}{P + Q}$ ; and the space through which it

has passed in the same time is  $s = \frac{Pgt^2}{P + Q}$ . Thus, for

example, if P and Q were equal to each other, then

$\frac{P}{P + Q} = \frac{1}{2}$ ,  $v = gt$ , and  $s = \frac{1}{2}gt^2$ .

The parts of the weight Q, which are uniformly disposed over the circumference A F G H, balance each other round the common centre of gravity S; their weight, therefore, has no effect in accelerating or retarding the descent of P; and this will be the case, whenever the axis of motion passes through the common centre of gravity. But in order to render the properties of rotatory motion more obvious, it will be convenient to dispose the parts of the revolving system, so that the axis of motion shall not necessarily pass through the common centre of gravity. Thus, referring to the preceding figure, instead of supposing the weight Q to be uniformly collected over the circular rim A F G H, let it be collected into any point Q. Here it is evident, that if the mass Q be acted upon by gravity, the force which communicates motion to the system round S will be variable; it being the greatest, when SQ is horizontal; and gradually diminishing, till Q has descended to its lowest point.

But in order to begin first with the simplest case, the

moving force should be constant, as it will be, if we suppose the mass that is collected in Q to be destitute of weight, and to possess inertia only: it follows, therefore, that during the revolution of Q round S as an axis, the moving force will be constantly equal to P, and the mass moved = P + Q, and consequently the force which accelerates the descending weight, or any point in the circumference,

will be that part of gravity which is expressed by  $\frac{P}{P + Q}$ , the same as before.

In these cases, the force which communicates motion to the system has been supposed a weight, or body, acted on by the earth's gravity, and consequently constitutes a part of the mass moved, at the same time that it acts as a moving force. But motion may be communicated by a force, which shall add nothing to the inertia of the matter moved; as, for instance, steam, muscular power, &c.: and it will, therefore, be convenient, in many investigations, to assume the moving force of this kind. The inertia of the moving force P, therefore, in the subsequent propositions, will not be taken into the account, unless expressly mentioned. Thus, if any number of bodies without gravity, being collected into the points F, H, Q, are caused to revolve round the axis S, by a moving force P, the force which accelerates these bodies in their revolution will be

$\frac{P}{F + H + Q}$ , when P is without inertia; or it will be

$\frac{P}{F + H + Q + P}$ , when P is possessed of inertia; the

bodies F, H, and Q, as also the power P, being supposed to act at equal distances from the axis of motion.

But when bodies revolve at unequal distances from the axis, their velocities being different, other formulae will be necessary for determining the force whereby any given point of the system is accelerated.

Let B (*fig. 2.*) represent a material point, moveable about an axis of motion passing through S: with the centre S, and distance SD, describe a circle D G H. Now if B be connected with every point in the area of the circle, which is an inflexible substance, no force can be applied to move the circle, but what must communicate the same angular motion to B. Let us suppose this force to be P, acting on the circumference of the inflexible circle D G H, by means of a line passing over the same, to which P is connected. Now the absolute force of P to move D, or any point in the circumference, will be P; but the communication of motion to this point D is resisted by the inertia of the body B, which being moved with a different velocity, and acted on by a different moving force, its inertia is not to be estimated by its quantity of matter only, but by considering what mass or quantity of matter which, when disposed at the distance SD, will oppose the same resistance to the descent of the weight P, as the body B itself does, when acting at the distance SB.

In order to estimate this, we must consider that when any two bodies are put in motion by two constant forces acting for the same time, the quantities of matter moved are in a direct ratio of the moving forces, and in the inverse

ratio of the velocities generated; that is, if  $\frac{M}{m}$  expresses

the ratio of the moving forces,  $\frac{Q}{q}$  that of the quantities of

matter, and  $\frac{V}{v}$  that of the velocities generated; the relation

# ROTATION.

tion of these quantities is defined by the equation  $\frac{Q}{q} = \frac{M}{m} \times \frac{V}{v}$ , by the laws of rectilinear motion. To apply this, it must be observed, that although the absolute force of the weight P, acting upon the point D, remains constantly the same, yet its effect upon bodies placed at different distances from the axis of motion are in the inverse proportion of those distances; therefore, the moving forces exerted by P, on the points B and D, will be in the proportion of SD to SB. Also, by the problem, the angular motion of D and B are equal; and, consequently, the velocity of B is to the velocity of D, as SB to SD. And since the quantities of matter in B, D, are in the direct proportion of the moving forces, or of SD to SB, and in the inverse proportion of the velocities generated, or of SB to SD, we shall have the quantity of matter in B to that contained in D, as  $SD^2 : SB^2$ ; and consequently the weight fought =  $B \times \frac{SB^2}{SD^2}$ .

The same may be otherwise found thus: let  $x$  = the quantity of matter required to be collected in D, M the moving force which acts on B,  $m$  that which acts on D, V the velocity of B, and  $v$  the velocity of D; then  $\frac{B}{x} = \frac{M}{m} \times \frac{v}{V}$ , but  $\frac{M}{m} = \frac{SD}{SB}$ , by the property of the lever; and  $\frac{v}{V} = \frac{SD}{SB}$ , by the nature of angular motion; therefore,  $\frac{B}{x} = \frac{SD^2}{SB^2}$ , and  $x = B \times \frac{SB^2}{SD^2}$ , as above.

Whenever, therefore, a body B revolves round an axis, by the action of a constant force P, applied at a given distance, SD, from the axis, in order to find the force which accelerates D, the mass B may be supposed to be removed, and instead of it an equivalent mass  $B \times \frac{SB^2}{SD^2}$  collected in the point D; to which the force is applied. After which, the acceleration of the point D, or any other point of the circumference, will be determined from the principles already explained; for the moving force being P, and the mass moved  $B \times \frac{SB^2}{SD^2}$ , the acceleration of P, or D, will be that part of gravity expressed by the fraction  $\frac{P}{B \times \frac{SB^2}{SD^2}}$ , while we suppose the power P void of inertia; or by  $\frac{P}{B \times \frac{SB^2}{SD^2} + P} = \frac{P \times SD^2}{B \times SB^2 + P \times SD^2}$ , when the inertia of P is considered.

On the same principle, if any number of bodies, A, B, C, &c. (*fig. 3.*) be put in motion round a fixed axis, passing through S, by a constant force P, applied at D, the point D will be accelerated in the same manner, and consequently the whole system will have the same angular velocity. If, instead of A, B, C, &c. placed at the distances SA, SB, SC, &c. we substitute the bodies

$\frac{A \times SA^2}{SD^2}$ ,  $\frac{B \times SB^2}{SD^2}$ , and  $\frac{C \times SC^2}{SD^2}$ ; these being collected into the points  $a, b,$  and  $c,$  respectively; and the moving force in this case being P, and the mass moved  $\frac{A \times SA^2}{SD^2} + \frac{B \times SB^2}{SD^2} + \frac{C \times SC^2}{SD^2}$ ; the force which accelerates D will be that part of the force of gravity that is expressed by the fraction,

$$\frac{P \times SD^2}{A \times SA^2 + B \times SB^2 + C \times SC^2};$$

or, if the inertia of P be considered, by

$$\frac{P \times SD^2}{A \times SA^2 + B \times SB^2 + C \times SC^2 + P \times SD^2}.$$

The velocity of the point D is uniformly accelerated, because the force above determined is invariable: it follows also, that the angular velocity of the system is uniformly accelerated, because the absolute velocity of any point at a given distance from the axis of motion, is as the angular velocity of that point, and consequently of the whole system. It is also manifest, that it is of no consequence whether the bodies A, B, C, &c. revolve in the same or different planes, if their distances from the axes SA, SB, SC, &c. are the same, these distances being estimated by lines drawn from A, B, and C, perpendicular to the common axis of motion; if, therefore, they should be situated in various planes, they may be referred to any one given plane perpendicular to the axis.

It is obvious likewise, that changing the position of the bodies A, B, C, in the same plane will not affect the force which accelerates the system, provided their respective distances from the axis of motion be not altered; thus, with the centre S, and distances SB, SC, let the arcs of circles be described; if B is transferred to  $b'$ , or C to  $c'$ , the moving force which acts on these bodies respectively will not be altered, and consequently the masses moved being likewise constant, the accelerating force will be the same.

All these propositions are equally true, whatever may be the force by which the angular motion is generated, provided it be constant; or, if variable, should its action be considered for an evanescent particle of time only.

We have here followed the method employed by Mr. Atwood in his treatise on "Rectilinear and Rotatory Motion;" being, as we conceive, the best calculated to convey a correct and elementary idea of the laws of rotatory motion. But it is obvious, that, instead of considering the given bodies A, B, C, (*fig. 3.*) to be equivalent to other bodies placed at the distance SD, we might enquire, at what distance from the centre of motion S all these bodies must be collected, without changing their masses, so that the same angular motion may be generated in the system? This point is called the *centre of gyration*; and as the method of finding this point has been already treated of under the article CENTER, we shall, in the subsequent part of this article, consider it as known, and shall proceed to the solution of a few such problems as appear best calculated for illustrating the subject under consideration.

## PROP. I.

Let D, E, F, (*fig. 4.*) represent a wheel, or cylinder, turning about an axis passing through its centre of gravity S; round the circumference of which a perfectly flexible line is made to pass, and to the end of which a body, P, is suspended;

# ROTATION.

pended; then, having given the radius  $SD$ , the power  $P$ , and the weight of the wheel, or cylinder,  $DEF$ , it is required to determine the angular velocity generated in the system in a given time.

Let  $R$  represent the centre of gyration, and make  $SR = r$ ,  $SD = d$ , the weight of the cylinder  $EDF = w$ , and the given power  $= p$ ; then the force which accelerates the point  $D$  is  $\frac{p d^2}{w r^2}$ , if we suppose  $p$  void of inertia; but if the inertia of  $p$  be considered, the force of acceleration is  $\frac{p d^2}{w r^2 + p d^2}$ , the force of gravity being assumed unity; but

if the force of gravity be taken  $16\frac{1}{2} = 193$  inches  $= l$ ; and  $3.14159 = c$ , then, in the time  $t$ , the velocity generated in the point  $D$ , or descending weight  $P$ , will be represented by

$$v = \frac{2 l t p d^2}{p d^2 + w r^2} \text{ inches in a second.}$$

And since the circumference of the circle  $EFD = 2 c d$ , the angular velocity generated in the time  $t$ , will be

$$\frac{360^\circ \times 2 l t p d^2}{2 c d (p d^2 + w r^2)} = \frac{360^\circ l t p d}{c (p d^2 + w r^2)} \text{ degrees, or}$$

$$\frac{l t p d}{c p d^2 + c w r^2} \text{ revolutions in a second.}$$

1. On the same principles it will be found, that the angular velocity generated in the system during the descent of the weight  $p$ , through any space  $S$ , is

$$\text{ang. vel.} = \sqrt{\left(\frac{l s p}{c^2 d^2 p + c^2 r^2 w}\right)} \times 360^\circ \text{ degrees, or}$$

$$\text{ang. vel.} = \sqrt{\left(\frac{l s p}{c^2 d^2 p + c^2 r^2 w}\right)} \text{ revol. in a second.}$$

2. The space described by the weight  $p$  in its descent from rest during  $t$  seconds, is  $s = \frac{l t^2 d^2 p}{d^2 p + r^2 w}$ , and consequently, the time of describing  $s$  is,

$$t = \sqrt{\frac{s d^2 p + s r^2 w}{l p d^2}} \text{ seconds.}$$

3. The space described by  $p$  from rest, while an angular velocity of  $n$  revolutions in a second is generated, is

$$s = \frac{n^2 c^2 d^2 p + n^2 c r^2 w}{l p}.$$

4. The force which accelerates the centre of gyration  $R$ ,

$$\text{is } f = \frac{p d r}{d^2 p + r^2 w}.$$

5. The absolute velocity generated in the weight  $p$ , while it descends from rest through the space  $S$ , is

$$v = \sqrt{\frac{4 l s p d^2}{d^2 p + r^2 w}}, \text{ and the velocity of the point } R, \text{ is}$$

$$v = \sqrt{\frac{4 l s p r^2}{d^2 p + r^2 w}}, \text{ and the velocity generated in the}$$

point  $R$ , in the time  $t$ , is

$$v = \frac{2 l t d p r}{d^2 p + r^2 w}.$$

All these results are drawn immediately from the known

formulae for accelerated motion, by making  $f = \frac{p d^2}{w r^2 + p d^2}$

the accelerating force, as determined in the preceding part of this proposition.

In the above investigation we have considered the revolving system to be a uniform wheel, or cylinder; but, it is obvious, the same will have place for any system of bodies, provided only that the axis of motion passes through its centre of gravity, and that  $R$  be the centre of gyration of the system.

## PROP. II.

Let  $ABC$  (*fig. 5.*) represent a wheel and axle, and let the axis be horizontal, having given its weight  $w$ , and the weight  $q$  applied to the circumference of the axle, and  $p$  applied to the circumference of the wheel, in order to raise  $q$ ; it is required to assign the space described by the elevated weight  $q$  from rest in any given time; the proportion of the radii of the wheel and axle being also known.

Here the absolute force which impels  $D$  is  $p$ , and since

$$q \text{ acts in a direction contrary to } p, \text{ with a force} = \frac{q \cdot SA}{SD},$$

this must be subtracted from  $p$ , which gives  $p - \frac{q \cdot SA}{SD}$

$$= \frac{p \cdot SD - q \cdot SA}{SD} \text{ for the motive force which impels}$$

$D$ . Let the centre of gyration of the wheel and axle be  $R$ ; then suppose the mass of matter in the whole system removed, if the mass

$$\frac{w \cdot SR^2 + q \cdot SA^2 + p \cdot SD^2}{SD^2}$$

be concentrated in  $D$ , the point  $D$  will be accelerated in the same manner, as when the parts of the system are disposed as described in the problem. Since, then, the force

$$\text{which impels } D = \frac{p \cdot SD - q \cdot SA}{SD}, \text{ it follows that}$$

this force, divided by the whole inertia, or the mass supposed to be concentrated in  $D$ , will give for the accelerative force on  $D = \frac{p \cdot SD^2 - q \cdot SA \cdot SD}{w \cdot SR^2 + p \cdot SD^2 + q \cdot SA^2}$ , and

$$\text{the accelerative force on } q = \frac{p \cdot SD \cdot SA - q \cdot SA^2}{w \cdot SR^2 + p \cdot SD^2 + q \cdot SA^2}.$$

Or, if we make  $SD = n$ ,  $SA = m$ ,  $SR = r$ , then the

$$\text{accelerating force on } D \text{ is } \frac{p n^2 - q m n}{w r^2 + p n^2 + q m^2}.$$

If the inertia of the wheel and axle is not considered,

$$\text{the above becomes} = \frac{p n^2 - q m n}{p n^2 + q m^2}. \text{ And if the inertia}$$

$$\text{of } p \text{ also} = 0, \text{ then we have } \frac{p n^2 - q m n}{q m^2}; \text{ or, if the mass}$$

moved have no weight, but possesses inertia only, as when it is drawn along a perfectly polished plane, as represented also

in *fig. 5*, then the accelerative force is simply

$$\frac{p n^2}{p n^2 + q m^2}.$$

Let this accelerative force in any of the cases we have supposed

# ROTATION.

supposed be put =  $f$ ; then the space, velocity, time, &c. will be found immediately from the general formula

$$s = \frac{1}{2} t v = g f t^2 = \frac{v^2}{4 g f}.$$

Suppose, for example,  $SD = n = 6$ ,  $SA = m = 2$ , then  $SR = r = 6 \sqrt{\frac{1}{2}}$ . (See *CENTER of Gyration*.) Let also  $w = 10$ ,  $p = 100$ ,  $q = 40$ . Then, by our first formula,

$$\frac{n^2 p - n m q}{w r^2 + p n^2 + q m^2} = \frac{36 \cdot 100 - 6 \cdot 2 \cdot 40}{10 \cdot 18 + 100 \cdot 36 + 40 \cdot 4} = \frac{3600 - 480}{180 + 3600 + 160} = \frac{3120}{3940} = \frac{156}{197},$$

the accelerative

force on D, that of gravity being 1. Whence the space passed through by the descending weight  $p$  in  $1''$ , is  $s =$

$$g f t^2 = \frac{156 \cdot 16 \frac{1}{2}}{197} \text{ feet, or } \frac{193 \cdot 156}{197} \text{ inches.}$$

Whenever motion is communicated to any body, a certain resistance must have been overcome by the moving force: this resistance is of various kinds. 1. The inertia of the mass moved, whereby it endeavours to persevere in its state of quiescence, or of uniform motion in a right line. 2. That of a weight, or other absolute force, opposed to the action of the moving power. 3. Obstacles upon which the moving body impinging is retarded in its progress; such, for example, is the resistance which arises from the particles of a fluid through which a body moves. The estimation of these resistances, and their effects in retarding the motion of bodies acted on by a given force, are deducible from the laws of motion, and constitute a part of the solution of almost every problem relating to the motion of bodies.

The moving forces also are of various kinds; *viz.* gravity, muscular power, the impact of bodies solid or fluid, &c.; and the effect of these moving forces, which are exerted on bodies in order to create motion, exclusive of the resistance opposed to them, depend on the various circumstances of the time in which they act, and on the spaces through which the bodies moved are impelled, &c. Whence it follows, that, from the great variety of undetermined conditions which may enter into mechanical problems, there must be of course various ways of producing the same mechanical effect; and it is a very material part of the art, considered either in a theoretical or practical point of view, to proportion the means to the end, and to effect this with all the advantages that the nature of the case is capable of. It is the due observation of these particulars, which contribute to render the mechanic instruments complete, and the neglect of them defective, in their construction. This proper choice of means to produce mechanical effect, is frequently the result of long and continued experience, independent of theory; the knowledge of which, however, when immediately applied to practice, would save the artist much time and trouble; and, at the same time, be productive of other advantages which experience alone must be destitute of.

### PROP. III.

In order to illustrate this application of theory to practice, let  $ABC$  (*fig. 5*) be a wheel and axle moveable round an horizontal axis, passing through  $S$ , and a given weight  $q$ , which applied to the circumference of the axle, to be raised by the application of a given moving force,  $p$ , which is applied to the circumference of the wheel; let it be required to assign the proportion of the radii of the wheel and axle, so that the time in which the weight  $w$  ascends through any given space shall be the least possible.

Let the given radius of the axle  $SA = m$ ,  $SR = r$ ,  $SD = x$ ; then, by the last proposition, the accelerative

force on  $p$  is  $\frac{x^2 p - q m x}{w r^2 + p x^2 + q m^2}$ , and that which accele-

rates  $q$  is  $\frac{m x p - m^2 q}{w r^2 + p x^2 + q m^2}$ ; the square of the time,

therefore, in which any space  $S$  is described by the ascending weight  $q$ , is

$$t^2 = \frac{s}{l} \times \frac{w r^2 + p x^2 + q m^2}{m p x - m^2 q}, \quad (l \text{ being} = 193 \text{ in.})$$

and which, by the question, is to be a minimum. And which, therefore, put into fluxions, and reduced, gives

$$x = \frac{m q + \sqrt{(m^2 q^2 + p w r^2 + q p m^2)}}{p},$$

the radius required.

Or, if we do not consider the inertia of the wheel, then

$$x = \frac{m q + \sqrt{(m^2 q^2 + q p m^2)}}{p}; \quad \text{if } p = q, \text{ then } x =$$

$m + m \sqrt{2} = m (1 + \sqrt{2})$ , the radius of the wheel in this particular case.

To give an example in numbers, let  $q = 100$ ,  $p = 33$ ,  $w = 20$ ,  $r = \sqrt{50}$ , or  $r^2 = 50$ ,  $m = 1$ , then the distance

$$\text{ought is } \frac{100 + \sqrt{(10000 + 33000 + 3300)}}{33} = \frac{315.17}{33}$$

$= 9.55$  inches.

This, therefore, will be the most convenient distance to apply the given moving force, when the chief object is to lessen the time of ascent. If it be required to assign the distance  $SD$ , when the momentum communicated to  $w$ , while it ascends through a given space, is the greatest possible, the solution will be the same as before, which, therefore, answers to two conditions; that is, it will render the time in which  $q$  ascends through a given space the least, and the momentum generated during the same ascent the greatest possible.

If the weight  $q$ , instead of ascending in a vertical direction, is drawn along an horizontal plane, as in *fig. 5*, the surface of which is supposed perfectly polished; then the weight  $q$ , as opposed to the moving force = 0, possessing in this case only inertia, we shall have for the radius of the wheel

$$x = \frac{\sqrt{(p w r^2 + p q m^2)}}{p} = \sqrt{\frac{w r^2 + q m^2}{p}}$$

which, if the inertia of  $w$  be rejected, becomes simply

$$x = \sqrt{\frac{q}{p}}.$$

Hence, if the quantity of matter to be drawn along the plane is four times greater than that which is contained in the moving force, the radius of the axle  $SA$  being given, in order that it may be impelled with the greatest velocity possible, and with the greatest momentum, the radius of the wheel should be double that of the axle, when the inertia of the wheel is not considered.

### PROP. IV.

As a further application of our theory, let  $ABC$ , (*fig. 5*) be a wheel and axle; when, having given a moving force or weight  $p$ , acting on the circumference of the

# ROTATION.

the wheel in order to raise a weight  $q$ , which is applied to the circumference of the axle, it is required to assign the quantity  $q$ , when the momentum generated in it in any given time shall be the greatest possible; the inertia of the wheel and axle not being considered.

Making, as before,  $SD = n$ ,  $SA = m$ , the force which accelerates  $q$  is  $f = \frac{nm\dot{p} - m^2\dot{q}}{n^2\dot{p} + m^2\dot{q}}$ ; therefore, if  $l = 193$  inches, the velocity generated in  $q$  in the time  $t$  will be  $2tl \times \frac{nm\dot{p} - m^2\dot{q}}{n^2\dot{p} + m^2\dot{q}}$ , and the momentum generated in  $q$  will be  $2tl \times \frac{nm\dot{p}q - m^2\dot{q}^2}{n^2\dot{p} + m^2\dot{q}}$ ; and as this is to be a maximum by the problem, its fluxion = 0, which being taken and reduced gives  $q = \frac{\sqrt{(n^2\dot{p}^2 + n^2m\dot{p}) - n^2\dot{p}}}{m^2}$ .

Therefore, if  $SD : SA :: n : 1$ , then  $q = \dot{p} \sqrt{(n^2 + n^2) - n^2}$ ; if the radius of the axle equal the radius of the wheel, that is,  $n = 1$ ; then the weight  $q = \dot{p} (\sqrt{2} - 1)$ , and consequently the weight moved must be about  $\frac{1}{2.7}$ ths of the moving force.

But if we introduce the weight of the wheel, and call it  $w$ ,  $r$  being the distance of the centre of gyration from the axis, then the momentum generated in the time  $t$  will be expressed

$$\text{by } 2lt \times \frac{nm\dot{p}q - m^2\dot{q}^2}{wr^2 + n^2\dot{p} + m^2\dot{q}}, \text{ which is the greatest possible}$$

$$\text{when } q = \frac{\sqrt{(n^2\dot{p}^2 + 2n^2r^2\dot{p}w + r^2w^2 + r^2nm\dot{p}w + n^2m\dot{p}^2) - (n^2\dot{p} + r^2w)}}{m^2}$$

## PROP. V.

Again, let  $ABCH$  (*fig. 7.*) be a system of bodies moveable round a vertical axis, which passes through the common centre of gravity of the system. And suppose  $DEG$  to be a wheel, the axis of which is vertical, and coinciding with that of the system; let motion be communicated by means of a line going round this wheel, the string  $DP$  being stretched by a given weight  $p$ ; let it be required to assign the radius of the wheel  $EGD$ , so that the angular velocity communicated to the system in a given time may be the greatest possible. Let the weight of the system =  $w$ , and the distance of the centre of gyration from the axis of motion =  $r$ , the radius sought  $SD = x$ ; then the motive force being  $p$ , the velocity generated in a given time in that

descending weight will be proportional to  $\frac{p x^2}{wr^2 + p x^2}$ , and

the angular velocity generated in the same time as  $\frac{p x}{wr^2 + p x^2}$ ,

which is to be a maximum by the conditions of the problem, we have, therefore,  $\frac{pwr^2\dot{x} + p^2x^2\dot{x} - 2p^2x^2\dot{x}}{(wr^2 + px^2)^2} = 0$ ,

whence  $pwr^2 = p^2x^2$ , or  $x = r \sqrt{\frac{w}{p}}$ , the distance sought.

Supposing, therefore, the moving force =  $\frac{1}{4}$  of the weight

of the system  $w$ , we shall have  $x = r \sqrt{\frac{w}{\frac{1}{4}w}} = 2r$ ; that is,

the weight should be applied at a distance from the axis, equal to twice the distance of the centre of gyration, in

order to produce the greatest angular velocity in a given time.

## PROP. VI.

In order to increase the action of a given moving force against a weight to be raised, or resistance to be overcome, a combination of two or more mechanic powers is frequently made use of. Thus, let  $p$  be a power applied by means of a line to the vertical wheel  $C$ , (*fig. 6.*), and suppose the circumference of the axle  $K$  to be in contact with the circumference of the wheel  $B$ , so that the circumference of the wheel  $B$  may always move equally fast with that of the axis which belongs to  $C$ ; let also the axle of  $B$  communicate motion to the vertical wheel  $A$ , to the axle of which a weight,  $q$ , is suspended, so as to act in opposition to  $p$ ; moreover, let  $lmn$  to 1, be the sum of the ratios of the radius of each wheel to that of its axle; then if  $p/mn = q$ , the two weights,  $p$  and  $q$ , will sustain each other in equilibrium; but if  $p/mn$  be greater than  $q$ , the equilibrium will be destroyed, and the weight  $q$  will ascend; and it is required to assign the space which, under those circumstances, will be described by  $q$  in a given time.

Let the radii of the wheel and axle  $A$  be in the ratio of  $l$  to 1; those of  $B$  as  $m$  to 1; and those of  $C$  as  $n$  to 1; the distance of the centre of gyration in  $A$  from the axis =  $r$ , the same of  $B = r'$ , and of  $C = r''$ ; the weight of the wheel and axle  $A = w$ ; that of  $B = w'$ ; and that of  $C = w''$ .

Now the absolute moving force is  $p$ , but since  $q$  acts in opposition to it, it must be subtracted from  $p$ , in order to obtain the real motive force of the system. And since  $q$

would balance a weight =  $\frac{q}{lmn}$ , if applied at  $p$ , the force which impels  $p$  on the whole will be  $\frac{p - \frac{q}{lmn}}{lmn}$ . In the

next place, the inertia which resists the communication of motion to  $p$  must be ascertained. Now motion is communicated to the wheel  $A$ , from the circumference of the axle  $B$ , and the inertia of  $A$ , and of the weight  $q$ , which resists the communication of a force applied at  $S = \frac{wr^2 + q}{l}$ ; in regard,

therefore, to the inertia of  $A$  and  $q$ , these may be supposed to be removed, and the equivalent mass  $\frac{wr^2 + q}{l}$  collected into

the circumference of the wheel  $A$ , or of the axle  $B$ . And since motion is communicated to  $B$ , by the circumference of the axle  $C$ , the inertia of  $B$ , together with

the equivalent mass  $\frac{wr^2 + q}{l}$  will be  $\frac{r'^2 l^2 w' + w r^2 + q}{l m^2}$ .

In like manner, since motion is communicated to  $C$  by the weight  $p$  acting at  $D$ , the inertia which resists the communication of motion to  $D$  or  $p$ , will be

$$\frac{p n^2 + w'' r''^2}{n^2} + \frac{r'^2 l^2 w' + w r^2 + q}{l m^2 n^2} = \frac{l^2 m^2 n^2 p + l^2 m^2 w'' r''^2 + r'^2 l^2 w' + w r^2 + q}{l^2 m^2 n^2}$$

and the force which accelerates  $p$  in its descent from rest

$$= \frac{l m n (p l m n - q)}{l^2 m^2 n^2 p + l^2 m^2 w'' r''^2 + r'^2 l^2 w' + w r^2 + q}, \text{ and}$$

## ROTATION.

and that which accelerates  $q$

$$= \frac{p l m n - q}{l^2 m^2 n^2 p + l^2 m^2 \omega'' r''^2 + r''^2 l \omega' + \omega r^2 + q}$$

if, therefore, we make this force =  $f$ , all the circumstances of the motion may be determined by the general formula

$$s = \frac{1}{2} t v = g f t^2 = \frac{v^2}{4 g f}; \text{ as before shewn. See a variety of other propositions in Atwood's treatise on "Rotatory Motion."}$$

In all the preceding propositions, the axis of the revolving system has been supposed fixed; but there are other cases by which rotatory motion may be produced, which ought to be attended to in this article; such as that which enue from a body descending down an inclined plane, having a ribbon or cord wound about it, one end of which is fixed at the upper part of the plane, which, by preventing the body sliding freely, causes a rotatory motion. The same effect also follows from the friction of the body against the plane; and the same may be imagined when there is no plane, but the body is left to fall freely, except so far as the cord wound about it shall produce a rotatory motion in its descent. We shall not attempt the investigation of these cases, but merely state the results that have been obtained; and must refer the reader for the former to the several treatises on dynamics, enumerated under the articles DYNAMICS and MECHANICS.

Let a body (*fig. 8.*) have a cord wound about it, either at its circumference, or any other part, as  $C$ , having one end fixed at a point above, as at  $D$ ; then if the body be left to descend by the action of gravity, it will acquire a motion of rotation by the unwinding of the cord, and the space actually descended by the body in this case, will be to the space descended in the same time, when falling freely, as  $CG$  to  $CO$ ;  $O$  and  $G$  representing the centres of oscillation and gyration when the point of suspension is at  $C$ . And the weight of the body will be to the tension of the cord, as  $CO$  to  $CG$ . The same ratios have place when the body descends down an inclined plane; the forces which generate the motion being both decreased in the same ratio.

The force by which spheres, cylinders, &c. are caused to revolve as they move down an inclined plane (instead of sliding), is the adhesion of their surfaces, occasioned by their pressure against the plane. This pressure is part of the weight of the body; for this weight being resolved into its component parts, one in the direction of the plane, the other perpendicular to it, the latter is the force of the pressure; and which, while the same body rolls down, the plane will be expressed by the cosine of the plane's elevation. Hence, since the cosine decreases, will the arc or angle increase. After the angle of elevation arrives at a certain magnitude, the adhesion may become less than what is necessary to make the circumference of the body revolve fast enough; and in this case, it will proceed partly by sliding, and partly by rolling; but the angle at which this circumstance takes place, will evidently depend upon the degree of adhesion between the surfaces of the body and plane. This, however, will never happen, if the rotation is produced by the unwinding of a ribbon, and it is on this latter supposition that the following particular cases are deduced.

Let  $W$  be the weight of the body,  $s$  the space descended by a heavy body falling freely, or sliding freely down a plane; then the space  $S$ , described by rotation in the same time, by the following bodies, will be in these proportions.

1. A hollow cylinder or cylindrical surface  $S = \frac{1}{2} s$ ; tension =  $\frac{1}{2} W$ .
2. A solid cylinder  $S = \frac{2}{3} s$ ; tension =  $\frac{1}{3} W$ .
3. A spheric surface  $S = \frac{3}{4} s$ ; tension =  $\frac{1}{4} W$ .
4. A solid sphere  $S = \frac{7}{8} s$ ; tension =  $\frac{1}{8} W$ . See Gregory's Mechanics, vol. i.

ROTATION, *Spontaneous*, is that rotatory motion which a body acquires when acted upon by any external force in free space. And the *centre of spontaneous rotation* is that point which remains at rest the instant the body receives its impulsion, or it is that point about which the body begins to revolve.

The most general method of treating this subject is with reference to three rectangular co-ordinates, after the method of Lagrange and other modern French writers; but as that method is not commonly adopted by English mathematicians, we must necessarily either enter at great length into explanation, or run the risk of not being understood by many of our readers, on which account we shall here adopt a similar mode of investigation to that which we have followed in the preceding part of this article.

First, then, we may observe, that when a body,  $B$ , (*fig. 9.*) of any shape whatever, receives an impulse, the direction of which does not pass through the centre of gravity, and takes in consequence two motions, as we have stated in the early part of this article, it is evident, that for an instant of time we may consider it as having only one motion, namely, a motion of rotation about a point or fixed axis,  $C$ , which may be either within the body, or out of it, according to its shape, and the distance,  $GS$ , between the centre of gravity and the direction of impact. If, while the line  $GS$  is carried parallel to itself from  $GS$  to  $G'S'$ , we imagine that it revolves about the moveable point  $G$ , as the particles of the body have greater or less velocities, as they are more or less distant from  $G$ , it is manifest that there is upon  $SG$  a certain point,  $C$ , which will be found to describe from  $C'$  towards  $C$  an arc equal to  $GG'$ , which, during an evanescent instant, may be regarded as a right line; in that case the point  $C$  will have been carried as far backward by its motion of rotation, as it will have been advanced parallel to  $GG'$  by the velocity common to all the parts of the body; the point  $C$  has, therefore, during this instant, been actually at rest in  $C$ ; and may consequently be considered as a fixed point about which the body during such instant has a rotatory motion. This point is the centre of spontaneous rotation, and is the same as the centre of suspension, corresponding to the centre of percussion, the centre of percussion being the point where the body is struck.

Without entering into a minute demonstration of this property, we may convince ourselves of its truth, by considering that the action of a body against an immoveable obstacle, in the centre of percussion, must have the same effect upon the body, as if that body had been at rest, and it had been struck by the obstacle; in which latter case, the centre of suspension would not be affected, and therefore it becomes the centre of spontaneous rotation. On which account it also follows, that the centre of spontaneous rotation is wholly independent of the magnitude of impact; but depends entirely on the distance that the force  $\varphi S$ , or the result of all the forces, acts from the centre of gravity,  $G$ ; and consequently, when that force acts in the direction, or coincides with  $GG'$ , there will be no motion of rotation, as is obvious.

We may also farther observe, that if an impact be made on any point of the axis of a symmetrical body, or a solid of revolution, and that point be considered as the point of suspension,

# ROTATION.

suspension, the corresponding centre of oscillation will be the centre of spontaneous rotation. This follows immediately from the properties of the centre of percussion and oscillation. (See CENTER.) To which we may also add, that since the force divided by the body acted upon, is a general expression for the velocity of the centre of gravity of that body; therefore the velocity of the centre of gravity of the body will be the same, whatever may be the direction of the impelling force; so that the permanency of the quantity of motion obtains the same in motions about a centre of spontaneous rotation, as in all other cases.

## PROP. I.

When  $\phi S$ , (*fig. 9.*) the direction of impact, passes through the centre of the impelling body, the centre of gravity of the body struck, will move with a velocity equal to the product of the quantity of motion of the impelling body into the distance between the centre of gravity and spontaneous rotation, divided by the sum of the products of the impelling body into the distance of the point of impact from the centre of spontaneous rotation, and of the impelled body into the distance of the impelled body, into the distance between the centres of spontaneous rotation and of gravity.

Let the quantity of matter of the impinging body be  $b$ , its velocity  $v$ , or  $bv = \omega$ ; and when the body  $B$  is struck in the direction  $\phi S$ , (in which the centre of the body  $b$  is always found), let the velocity of its centre of gravity be  $V$ , the centre of spontaneous conversion being at  $C$ . Then  $CG : CS :: V : \text{the velocity of the point } S$ , which is therefore  $V \cdot \frac{CS}{CG}$ ; consequently,  $v - V \cdot \frac{CS}{CG}$  = the velocity lost by  $b$  in the direction  $\phi S$ ; whence, by the third law of motion,  $b \times \frac{v \cdot CG - V \cdot CS}{CG} = B \cdot V$ , and by reduction,  $V = \frac{b \cdot v \cdot CG}{B \cdot CG + b \cdot CS}$ , as was to be demonstrated.

Hence, if the inertia of the striking body be evanescent, the velocity  $V$  will become  $\frac{bv}{B} = \frac{\phi}{B}$ , being the same as would be generated if the body  $b$  impinged directly on it with the velocity  $V$ .

## PROP. II.

The inertia of the striking body being evanescent, the angular velocity of the system about the centre of gravity is equal to the momentum of the impelling body, divided by twice the product of the mass of the impelled body, and the distance  $CG$ , into the periphery of a circle whose diameter is unity.

If the fixed axis passed through  $C$ , the centre of gravity would describe a circle, whose radius is  $CG$ , with the velocity  $\frac{bv}{B}$ . But, in the present case, the motion of the system will be compounded of the uniform rectilinear motion of the centre of gravity, in the direction  $G'C$ , perpendicular to  $CS$ , and the angular motion  $\times G'p = GCG'$ , generated round the centre of gravity. And since the periphery of a circle, whose radius is  $CG$ , is  $2\pi \cdot CG$  ( $\pi$  being  $= 3.1416$ ), we have this analogy,  $\frac{bv}{B} : 2\pi \cdot CG$

$$:: 1'' : \frac{2\pi \cdot B \cdot CG'}{bv}, \text{ the time of one revolution in seconds.}$$

Whence it follows, that the number of revolutions, or parts of a revolution, in a second, or the angular velocity  $U$ , will be  $1 \div \frac{2\pi \cdot B \cdot CG}{bv} = \frac{bv}{2\pi \cdot B \cdot CG}$ .

And since  $C$  is the centre of percussion to  $S$  as a centre of motion, if  $Q$  be the centre of gyration with respect to  $G$  as a centre of motion (that is, if  $Q$  be the principal centre of gyration), we shall have  $GC \cdot GS = GQ^2$ , or  $CG = \frac{GQ^2}{GS}$ . This value of  $GC$  being substituted for it in the

preceding expression for the angular velocity, it becomes

$$U = \frac{b \cdot v \cdot GS}{2\pi \cdot B \cdot GQ^2}. \text{ It follows also from what is shewn above,}$$

that the centre of spontaneous rotation, during the motion of the system, describes the common cycloid. For the motion of any point in the system is compounded of the uniform rectilinear motion of the centre of gravity, and of the angular motion generated round that centre; but the velocity with which the centre of spontaneous rotation would move round the centre of gravity, if there only existed a rotatory motion in the system, would be equal to that with which the centre of gravity would move round it, if the centre  $C$  were fixed; consequently, since the centre  $C$  has both a rotatory and progressive motion, each of which is equal to that of the centre of gravity, it will describe a cycloid.

## PROP. III.

In the body, or system  $B$ , (*fig. 9.*) to which, when quiescent, motion has been communicated by the impulse of a force,  $\phi$ , without inertia, that is, rectilinear motion to the centre of gravity measured by the space  $V$ , which that centre would describe uniformly in any given time, and angular motions measured by the revolutions  $U$ , or parts of a revolution, which it would describe uniformly round  $G$  in the same time; then if the notations in the preceding propositions be retained, and  $Q$  be the principal centre of gyration, when the system revolves about its centre of gravity, the perpendicular distance from the centre of gravity, at which the impelling force must act so as to have generated these progressive and rotatory motions,

$$\text{will be } GS = \frac{2\pi \cdot U \cdot GQ^2}{V}.$$

Let  $\phi S$  be the direction of the impulse, and let  $\phi$  be equal to the momentum of an evanescent body  $b$ , moving with the velocity  $V$ ,  $B$  being the weight of the system; then the velocity communicated to the centre of gravity of

$$\text{the system, will, by the last proposition, be } = \frac{b \cdot v \cdot SG}{2\pi \cdot B \cdot GQ^2}.$$

But by the proposition, the velocity communicated to the centre of gravity of the system is  $V$ ; and the angular motion, that is, the number of revolutions, or parts of a revolution, described while the centre of gravity passes over the space  $V$ , is  $U$ ; so that from the conditions there arises this

$$\text{equation, } U = \frac{b \cdot v \cdot GS}{2\pi \cdot B \cdot GQ^2} = \frac{V \cdot GS}{2\pi \cdot GQ^2}, \text{ by putting } V$$

$$\text{for its equal } \frac{bv}{B}. \text{ Hence } GS = \frac{2\pi \cdot U \cdot GQ^2}{V}.$$

# ROTATION.

If the body  $B$  be a sphere, whose radius is  $r$ , then  $GQ^2 = \frac{2}{3}r^2$ , and if  $u$  be the absolute velocity of rotation of an equator of the sphere, we have  $U = \frac{u}{2r}$ ; whence the preceding value of  $GS$  is transformed to this,  $GS = \frac{2}{3}r \cdot \frac{u}{V}$ .

This proposition may be applied to the double motion of the planets. The earth revolves about an axis passing through its centre of gravity, while, by a motion of translation, that centre is carried on in free space in an orbit nearly circular; and a similar kind of double motion has been discovered in several of the planets, and analogy leads us to believe it obtains in the others. Now, supposing the bodies of the planets to be spherical, as they are nearly, the use of this proposition at once appears. Having given, for instance, the magnitude of an impulse, with respect to the mass of the earth, and the direction  $\angle S$ , in which it was applied, at any given distance  $SG$  from the centre of gravity, the angular motion round  $G$  would be inferred; and conversely if the actual rotatory velocity of the earth's equator, and the velocity in its orbit, be ascertained, the distance  $GS$  from the centre, at which it may have received a single impulse  $\angle S$  adequate to produce the double motion, may be readily found.

Thus, any point in the earth's equator passes over 25,020 miles by rotation in one sidereal day; and if the mean distance of the earth from the sun be 95 million miles, the earth will pass over nearly 596,904,000 miles by its orbital motion in a year, or in about 366 sidereal days; hence  $596,904,000 \div 366 = 1,630,852$ , will be equal to  $V$  in our theorem, while  $25,020 = u$ . Consequently,  $GS = \frac{2}{3}r \cdot \frac{u}{V} = \frac{r}{163.2}$ .

So that if an impulse be impressed upon a quiescent sphere, and the direction of force should be at a distance  $SG$  from its centre of gravity of about  $\frac{1}{163.2}$  part of its radius, the angular motion of that sphere, and the absolute motion of its centre, will have the same relation to each other, as those which actually obtain in the earth.

The time of the rotations of Mercury, Uranus, and the last new planets, are unknown; but for the following planets it is ascertained, so that, by the same theorem, we obtain these values of  $GS$ ; viz. Mars,  $\frac{r}{195}$ ; Jupiter,

$\frac{r}{2,8125}$ ; Saturn,  $\frac{r}{2,588}$ ; the Moon,  $\frac{r}{555}$ .

We have not sufficient data for the sun; but the very circumstance of his having a rotation of  $27^d 7^h 47^m$ , makes it very probable that he, with all his attendant planets, is also moving forward in celestial space, perhaps round some centre of still more general and extensive gravitation; for the perfect opposition and equality of two forces, for giving a rotation without a progressive motion, has the odds against it of infinity to unity. This corroborates the conjectures of philosophers, and the observations of Herschel and other astronomers, who think that the solar system is approaching to that quarter of the heavens in which the constellation Aquilea is situated.

## PROP. IV.

If a body revolves about an axis passing through its centre of gravity with the angular velocity  $U$ , while this axis is carried round another axis, also passing through its centre of gravity, with the angular velocity  $U$ , these two motions compose a motion of every particle of the body, round a

third axis lying in the plane of the other two, and inclined to each of the former axes in angles whose sines are inversely as the angular velocities round them; and the angular velocity  $V$  round this new axis, is to that about one of the primitive axes, as the sine of the inclination of the latter axis, to the sine of the inclination of the new axis to the other primitive axis.

Thus, if a body turns round an axis  $AGa$ , (*fig. 10.*) passing through its centre of gravity  $G$ , with the angular velocity  $U$ , while this axis is carried round another axis  $BGb$ , with the angular velocity  $u$ ; and if  $GD$  be taken to  $GE$  as  $U$  to  $u$ , (the points  $B$  and  $E$  being taken on that side of the centre where they are moving towards the same side of the figure,) and the line  $DE$  be drawn, the whole and every particle of the body will be in a state of rotation, about a third axis  $CGc$  parallel to  $DE$ , lying in the plane of the other two, and the angular velocity  $v$  about the axis  $CGc$ , will be to  $U$  as  $DE : DG$ ; and to  $u$  as  $DE : GE$ . For let  $P$  be any particle of the body, and suppose a spherical surface, whose centre is  $G$ , to pass through  $P$ . Draw  $PR$  perpendicular to the plane of the figure; then is  $PR$  the common section of the circle of rotation  $IP$ ; round the axis  $Aa$ , and the circle  $KPk$  of rotation round the axis  $Bb$ . Let  $F$  and  $O$  be the centres of these circles of rotation, and  $Ii$ , and  $Kk$ , their diameters. Draw the radii  $PF$ ,  $PO$ , and the tangents  $PM$ ,  $PN$ ; these tangents are in the plane  $MPN$ , which touches the sphere in  $P$ , and the plane of the axis in the line  $MN$ , to which a line drawn from  $G$ , through  $R$ , would be perpendicular. Suppose  $PN$  to represent the velocity of rotation of the point  $P$ , about the axis  $Bb$ , while  $Pf$  represents its velocity of rotation about  $Aa$ , and complete the parallelogram  $PNI f$ ; then is  $Pt$  the direction and velocity of the resultant of the composition of  $PN$ ,  $Pf$ , and it is manifestly in the same plane as the constituent lines. Let perpendiculars  $fF$ ,  $tT$ , be drawn to the plane of the axis, and the parallelogram  $PNI f$  will be orthographically projected on that plane, its projection being also a parallelogram  $RNTF$ . Draw the diagonal  $RT$ . Then, since  $PR$  is perpendicular to the plane of the primitive axis,  $PRtT$  is so likewise; and consequently the compound motion  $Pt$  is in the plane of a circle of revolution about some axis situated in the plane of the other two. Produce  $IR$ , and draw  $GC$  intersecting it perpendicularly in  $H$ ; and let  $LPl$  be the circle of rotation, its diameter being  $Ll = 2LH$ ; then is  $Pt$  a tangent, and perpendicular to  $PH$ , and it will meet  $IR$  in some point  $Q$  of the line  $MN$ . The particle  $P$  is in a state of rotation about the axis  $CGc$ ; its velocity is to the velocities round  $Aa$ , or  $Bb$ , as  $Pt$  to  $Pf$ , or  $Pt$  to  $PN$ . Now  $PN$  the tangent is perpendicular to  $OP$ , and  $PR$  is perpendicular to  $ON$ ; therefore  $OP : PN :: PR : RN$ , or

$$RN = \frac{PN \cdot RN}{PO}. \text{ But the velocity of } P \text{ about the axis } Bb, \text{ is } u \cdot OP; \text{ whence } RN = \frac{U \cdot OP \cdot PR}{OP} = u \cdot PR.$$

In like manner,  $RF = U \cdot PR$ ; consequently  $RF : RN :: U : u :: GD : GE$ . But  $NT : RN :: \sin. NRT : \sin. NTR :: \sin. GED : \sin. GDE$ ; hence  $\sin. NRT : \sin. NTR :: \sin. GED : \sin. GDE$ . Now, since  $NR$  is perpendicular to  $EG$ , and  $NT$  (parallel to  $FI$ ) perpendicular to  $DG$ , we have  $RNT = EGD$ . Hence  $TR$  is perpendicular, and  $Cc$  parallel to  $ED$ . Also, since  $RN$ ,  $RF$ ,  $RT$ , are as the velocities  $u$ ,  $U$ ,  $v$ , about these different axes, and vary respectively, as  $EG$ ,  $DG$ ,  $DE$ , we have  $v : U :: ED : GD : GE$ ; which was to be demonstrated.

Hence, if every particle of a body, whether solid or fluid, receives at the same time two separate impulses, the

one competent to the production of a motion of the particle round an axis with a certain angular velocity, and the other competent to the production of a rotatory motion about another axis with a certain velocity, the combined effect of all these impulsions, will be a motion of the whole system about a third axis, given in position, with an angular velocity which is also given; and this motion will obtain, without any separation or disjunction of parts, except such as may be occasioned by the action of the centrifugal forces resulting from the rotation.

Hence, also, if a body be turning round any axis, and every particle, in one instant, get precisely such an impulse as is competent to produce a given angular velocity round another axis, the body will turn round a third axis given in position, with a given angular velocity.

Lastly, when a rigid body acquires a rotation about an axis, by an impulse on one part of it, and either at the same time, or afterwards, receive an impulse on any part which alone would have produced a certain rotation about another axis, the joint effect of these impulses will be a rotation about a third axis, in conformity with this proposition. For when a rigid body acquires a motion about an axis, not by the simultaneous impulse of the precisely competent force on each particle, but by an impulse on one part, there has been propagated to every particle, (by means of the cohesive forces,) an impulse precisely competent to the production of that motion which the particle actually acquires; and when a rigid body already turning round an axis *A a*, receives an impulse which makes it actually turn about another axis *C c*, there has been propagated in each particle a force precisely adequate to the production, not of the motion but of the *changes* of motion which takes place in that particle; that is, a force which, when compounded with the inherent force of its primitive motion, produces the new motion, that is, by the proposition a force which alone would have caused it to turn about a third axis *B b*, with a rotation making the other component of the actual rotation about *C c*.

This elegant theorem, the enunciation of which is due to P. Frisi, is very important, and gives a great extension to the doctrine of the composition of motion. It is of great use in many curious problems, and particularly that of the precession of the equinoxes. Those who wish for farther information on the subject of rotatory motion, may consult Gregory's "Mechanics," from which we have taken the three last propositions; Simpson's "Tracts;" Frisi's "Cosmographia;" "Philosophical Transactions," 1780; Landen's "Memoirs;" Atwood "On the Rotatory Motion of Bodies;" Lagrange's "Mécanique Analytique;" and a memoir "Sur le Mouvement de Rotation," by François, Paris, 1813; in which latter work the subject is treated with all the generality it seems to admit of, and which method we should have adopted in this article, but for the reasons stated in the commencement of it, that is to say, the length to which we must have extended it, in order to have rendered it intelligible to the English reader.

ROTATION is also synonymous with ROLLING, which see.

ROTATION, in *Geometry*, the circumvolution of a surface round a line, called the *axis of rotation*.

By such rotation of planes, the figures of certain regular solids are formed or generated.

The method of cubing solids, generated by such rotation, is laid down by M. de Moivre, in his specimen of the use of the doctrine of fluxions. For the fluxions of such solids take the product of the fluxion of the abscissa, multiplied by the circular base, and suppose the ratio of a square to

the circle inscribed to be as  $\frac{n}{1}$ ; the equation expressing the nature or property of any circle, whose diameter is *d*, is  $y y = d x - x x$ . Therefore  $4 \frac{d x x - x^2 x}{n}$  is the fluxion of a portion of the sphere, and consequently the point itself  $4 \frac{\frac{1}{2} x d x - \frac{1}{2} x^2}{n}$ , and the circumscribed cylinder is  $4 \frac{d x x - x^2}{n}$ ; therefore the portion of the sphere is to the circumscribed cylinder as  $\frac{1}{2} d - \frac{1}{2} x$  to  $d - x$ . Phil. Transf. N<sup>o</sup> 216.

For other instances of this kind, and a view of the application of the doctrine of fluxions, to find the contents of solid bodies, see SOLIDITY. See also CENTROBARYC Method.

ROTATION, *Revolution*, in *Astronomy*. See REVOLUTION.

ROTATION, *Diurnal*. See DIURNAL, and EARTH.

ROTATION, in *Anatomy*, the action of the muscoli rotatores; or the motion which they give to the parts they are fixed to.

There are two muscles, the great and the little obliquus, used to perform the rotation of the eye. The obturator internus and externus effect the rotation of the thighs.

Mr. Winslow has given an account of this, as well as of pronation, and other circulatory animal motions. See Mem. de l'Acad. des Sciences, 1729. See also EXTREMITIES.

ROTATION of *Crops*, in *Agriculture*, the several means of cropping lands of the arable kind in such a manner as to prevent their being exhausted as much as possible, and at the same time to preserve them free from weeds in the most complete and perfect mode. The proper alternation of different sorts of crops in this intention, is a matter of vast importance to the interests of agriculture, and in which immense improvements have been made in this and other countries within this last half century, but which is still far from any thing like perfection. See *Course of CROPS*.

In addition to what has been stated under the head referred to above, it may be observed, in this place, that the nature and state in which the manure is, when applied to the lands, should likewise be attended to in fixing the rotations of the crops, in order that the first and all the succeeding ones may be supported in the best and most effectual manner by the changes that are always taking place afterwards in such materials, when united and incorporated with the soils; and in this way, those parts of them which are not fitted to or suitable for one kind of crop, may be converted to the nourishment and support of the next, and so on in the same manner. Thus, where the turnip is the first crop in the rotation, and manure of the fresh dung kind is used, which directly affords it the necessary supply of soluble matter, while the heat which is generated in its decomposition assists the sprouting and growth of the seed, it should be succeeded by barley, or some other similar sort of grain crop, with suitable grass seeds, as the land will have been but little robbed of its fertility by the preceding turnip crop, and of course will plentifully supply the soluble portions of the gradually decomposing substance of the manure to that crop; while the grasses that remain on the land, which, in many cases, draw only a small portion of the matter of which they are composed from the earth, and in all probability take up the gypseous substance contained in the manure, which would be of little utility to other sorts of crops, and

and which, in consequence of their large supply of leaves, derive a considerable proportion of their nutriment from the surrounding atmosphere, when they become ultimately ploughed down into the ground, afford a considerable supply of manure to the succeeding wheat crop, by the gradual decay and decomposition of their roots and leaves, and besides, the woody fibrous parts of the farm-yard manure, which was at first applied, and which contains in its composition the phosphate of lime, as well as some other soluble parts which are of difficult reduction, are now broken down, and brought into a suitable state for the support of that crop.

After this deteriorating and exhausting crop has been taken from the ground, recourse must again be had to fresh manure, and the rotation be renewed.

And in the strong clayey soils, after the land has remained for two years in the state of grass, from the time of taking a well fresh dunged soil for barley crop, the leys may be ploughed down and sown with pea and bean crops; after which the pea and bean stubble may be turned in for a wheat crop; and in many cases this may be followed by crops of winter tares and winter barley to be eaten off upon the land in the spring season, previously to its being prepared by their being ploughed in, and other means for the sowing of turnips.

In these cases, the rotation may cease and begin again, either after taking the wheat crop, or those of the tares and winter barley, according as the circumstances of the different cases may be in respect to the land.

It may be noticed, that pea and bean crops, in all cases of this nature, appear to be very well suited to form and prepare the land for wheat crops, as is clearly ascertained, from their being alternately cultivated for many years together in some such situations. This may probably depend, in some measure, upon the small proportion of substance similar to that of albuminous matter which they contain, and afford, as well as upon the principles supplied by the decay of the bean roots in the ground, which may be capable of forming a part of the glutinous material in wheat crops.

In the business of cropping lands, it may likewise be necessary to have regard to the nature and manner in which the different sorts of plants are fed and supported, for though the composition of them in general may be very similar, the specific differences in the products of a number of them, as well as many other facts and circumstances, fully demonstrate that they must draw different sorts of matters from the earth or soil, and although it must be obvious that such vegetables as have the smallest supplies of leaves, will, in proportion, be the most exhausting to the earth or soil of its common nutrient materials, yet that particular sorts of plants, as they are principally supported by particular kinds of matters, will, where their produce is carried off the land, require peculiar principles of such natures to be supplied to the soil on which they grow.

The case of the potatoe, as well as some other plants, is highly illustrative of this point, as it is well known that it produces the most fully, and in the most luxuriant manner at first, while the ground or mould is in a fresh or virgin state, and just turned up from old ley or pasture; but that in the course of a few years it degenerates and declines, standing in need of a new fresh soil; and the nature of its production has a constant tendency to search for this, as the fibrous radicles afford new bulbs or roots at a considerable distance from the old plant.

Such grounds also as have been long cropped with some kinds of artificial grasses, as red clover, &c. frequently cease to yield good and full crops of them; they becoming,

in the language of the farmer, sick of, or tired with them; one principal and probable reason of which is, perhaps, the deficiency or absolute want of the peculiar sort of material which is necessary for their growth and support, as above, which in this instance is that of gypsum. This, therefore, may be proper to be regarded in determining the rotations in such cases.

A most remarkable case of this property and capability of particular plants to drain and exhaust the land of the particular principles and substances suited to their growth and support, is met with in the mushroom tribe, which are asserted never to appear in succession on the same point of ground.

In short, in every rotation of crops, it is of essential importance that every part of the land should, in its turn or succession, be made to contribute, as fully as it is capable, to the different plants as crops, by their being properly chosen and adapted in this respect.

In many instances of strong loamy land, great benefit may be derived from cropping with beans, which have been fully dunged for, after barley and clover, as the latter of the above crops and the manure will supply abundant support for the bean crop, and that crop, in its stubble and roots, afford an admirable preparation and supply of food for wheat, as already noticed; which may be properly and beneficially succeeded by tares, which again prepare the ground well by their being fed off on the land, or soiled for another crop of wheat. The rotation may then begin again.

Some think that all plants, the seeds of which yield oil, exhaust land in a very high degree. Thus cole, which is a sort of cabbage, especially when it perfects its seed, as well as the cabbage itself, which is believed by many to deteriorate the land greatly, is improper as a crop in preparation for wheat, though it is had recourse to in many districts, and thought highly of for that purpose. Great caution is constantly necessary in the rotations of cropping with such sorts of plants as crops.

In some cases of the lighter kinds of mixed soils, peas are found full as good a preparation for the wheat crop as beans, having the advantage of being off the land so much sooner. Pease or tares also prepare well for wheat, after ray-grass, on the stone-brash lands in many instances, when well cultivated.

That bean crops should always precede the wheat, and not follow it, as is too frequently the case in a number of districts, is sufficiently evident from the above remarks. Peas may sometimes be substituted in the place of the bean crop, with considerable propriety and utility.

It may be concluded on this most interesting subject, that of all the signs which denote the progress or perfection of the art of husbandry in any district or country, there is none which is more certain and correct than that of the rotations of the crops, which are pursued by the farmers in the management of their arable lands. Where there is no regular and appropriate change in the kinds of the crops, so as to suit them to the nature of their support, and the states and circumstances of the land, the system of farming must be in a wretched state indeed; but where the arable grounds are regularly preserved in a productive state, by suitable rotations well applied, not only the interest of the tenant is promoted, his judicious conduct rendered evident, and the advantage of the proprietor secured by the improvement which is effected, but the good of the community greatly increased, by the products of the earth being rendered so much more abundant for its use and support.

The practice of applying manure and cropping, so as to

draw out the strength of it, and that of the soil, as soon as it can be done, until the land is rendered quite barren and incapable of affording any more produce without some respite, is most miserable, and deserves the highest reprobation, though not uncommon.

It has been contended, that a well-selected rotation of crops is capable of doubling the support of the present population, and of vastly increasing the wealth and resources of the nation. Also, that having recourse to proper modes of cropping, may sometimes be highly beneficial in preventing the rust or mildew in wheat, as over-dunging immediately for such crops, is found to be productive of the disease, while the application of it previously to some sort of smothering crop, such as rape or cole in strong lands, and potatoes on those that are light, is an almost effectual means of avoiding it. Some maintain that this disease seldom or ever takes place in wheat crops after rape or cole, and others assert the same to be nearly the case in them after potatoes. And that, as wheat after clover on light soils is liable to be affected in this way, it may occasionally be of importance to take it before that crop somewhat in this manner, potatoes, wheat, clover, barley.

**ROTATION of Crops, in Gardening,** the introduction of the most proper and suitable courses of crops, for the production of good garden vegetables of different kinds, and for the keeping of the ground in the richest and most proper condition for the cultivation and growth of them. This is equally important and necessary in the garden as in the field, but it cannot, by any means, be so fully and effectually accomplished in the former as in the latter, on account of the smallness of the usual limits of it, and the greatness of the number of different articles which are required to be raised and cultivated, as well as their more intimate relation to each other. See **CROPS, Course of.**

In addition to what has been said under the head above alluded to, it may be observed, that the management of this business may, in some measure, be effected by a suitable division and arrangement of the cultivated culinary vegetables into different classes, as crops for the purpose, as their natures, habits, methods of culture, and difference in duration and other circumstances may indicate. And by the application of the manure which is used in such states, kinds, and manners, as that it may go the farthest, be consumed to the greatest advantage in the raising of the different sorts of vegetables in succession, and produce them of the best and most healthy kinds.

Manure should be applied in the first instance only for those crops that are not injured in any way by it, but which receive great benefit from its use, and cannot be grown well without its being always employed in such states as are most favourable to them, according to their different natures, habits, and kinds, as the potatoe, cabbage, bean, celery, &c. When these crops have taken up the more gross parts, the finer and more delicate vegetables may succeed on the same land in their proper order, so as to consume the remaining parts of the manure in the most advantageous ways, both to the produce and the land.

On this principle, the rotations should obviously begin either with the potatoe, cabbage, bean, celery, or some other crop of a similar kind, well manured for; and be followed by those of the more delicate sorts, in their most suitable courses, so as not to be hurt in their growth or flavour. The use of grass seeds on well manured land may also sometimes be had recourse to by market gardeners, for laying down their lands in the view of refreshing them, and soon breaking them up again.

By proper attention to the different circumstances which

have been noticed above, and others of the same nature that may occur, different useful and advantageous rotations of crops may be introduced into garden culture, and the art be, in this way, very greatly improved.

**ROTATOR,** in *Anatomy*, a name given to the oblique muscles of the eye, called also, from the direction of the fibres, *circulares*, and from the effect of their action, *amatorii*. See **EYE**.

**ROTCHET,** in *Ichthyology*, an English name for the fish called by authors *cuculus*, and more frequently by us the red gurnard. See **TRIGLA Cuculus**.

**ROTE,** an old musical instrument, frequently mentioned in the French Fabliaux, and supposed to mean the *walle*, an instrument played with a wheel, instead of a bow.

**ROTE,** in *Geography*, a river of Germany, which runs into the Itch, two miles N. of Coburg.

**ROTEBRO,** a town of Sweden, in the province of Upland; 30 miles N.N.W. of Stockholm.

**ROTELE,** in *Ichthyology*, a name by which some call the *rutilus latior*, or *rubellus fluviatilis*, more frequently known by the name of the roach, a river-fish, with red belly-fins and tail. See **CYPRINUS Rutilus**.

**ROTELSEE,** in *Geography*, a town of the duchy of Wurzburg; 4 miles E. of Kitzingen.

**ROTENBACH,** a town of the archduchy of Austria; 9 miles N.W. of Schwanastadt.

**ROTENBERG,** a town of Austria; 18 miles S.W. of Freystadt.

**ROTENBURG,** a town of Switzerland, in the canton of Lucerne; 4 miles N. of Lucerne.—Also, a town of Wurtemberg, on the N. side of the Neckar, opposite to Ehingen; 21 miles S.W. of Stuttgart. N. lat. 48° 32'. E. long. 9° 3'.—Also, a town of Germany, in the county of Verden, on the Wumme; 12 miles N.N.E. of Verden. N. lat. 53° 8'. E. long. 9° 24'.—Also, a town of Germany, in the principality of Hesse, on the Fulda; 25 miles S.S.E. of Cassel. N. lat. 51° 1'. E. long. 9° 42'.—Also, a town of Brandenburg, in the New Mark, on the Oder; 12 miles E.S.E. of Crossen. N. lat. 52° 5'. E. long. 15° 30'.—Also, a town of the duchy of Baden; 14 miles E.S.E. of Spire. N. lat. 49° 15'. E. long. 8° 48'.—Also, a town of the duchy of Magdeburg; 40 miles S. of Magdeburg.

**ROTENSTEIN,** a town of the duchy of Carinthia; 10 miles S.W. of Saxenburg.

**ROTGANS, LUKE,** in *Biography*, an eminent Dutch poet, was born of a good family at Amsterdam, in 1645. His education led him to the cultivation of polite literature, which, for a time, he quitted to take up arms in defence of his native country, when invaded by the French in 1672. When his services were no longer required, he retired to a villa between Amsterdam and Utrecht, where he resumed with new vigour his favourite pursuits. When peace was concluded between France and Holland, he paid a visit to Paris. He died of the small-pox in 1710, in the 66th year of his age. He was author of a number of poems, highly esteemed in his own country. Of these, one is a "Life of William III.," in eight books. His other pieces are moral and miscellaneous, which, with two tragedies, were printed, in 1715, at Lewarden.

**ROTH,** in *Geography*, a town of Germany, in the principality of Anspach, at the union of the Roth and Rednitz, containing an asylum for those who have been guilty of manslaughter; and manufactures of stockings, Spanish lace, and stuffs; 15 miles S. of Nuremberg. N. lat. 49° 10'. E. long. 10° 59'.—Also, a river of Germany, formed from two springs, called the Ober and the Unter Roth, which unite

unite near Hilpoltstein, on the borders of Franconia; and after this union, it falls into the Rednitz, near the town of Roth.—Also, a river of Bavaria, which rises about 10 miles S. of Landeshut, and runs into the Inn, opposite to Scherding.—Also, a town of Germany, in the lordship of Limberg; 4 miles W.N.W. of Gaildorf.—Also, a river of Germany, which runs into the Danube, S.W. of Leipzigheim.

ROTH, *Ajesh*, a town of Bohemia, in the circle of Prachattitz; 4 miles N.E. of Pisek.

ROTH, *Haus*, a town of Silesia, in the principality of Neisse; 7 miles E.N.E. of Neisse.

ROTHA, a town of Saxony, in the circle of Leipzig; 6 miles S. of Leipzig. N. lat.  $51^{\circ} 12'$ . E. long.  $12^{\circ} 21'$ .

ROTHALS, in *Ornithology*, a name given by Gesner, and some others, to the pochard, or red-headed wigeon, the *anas ferina*; a bird distinguished from all others of the duck-kind, by having no variegation in its wings. See DUCK (FERINA).

ROTHARIS, in *Biography*, king and legislator of the Lombards, was duke of Breiscia, at the time of the death of king Ariovald, in the year 638, who left a widow, named Gundeburg, but no male issue. The Lombards gave this lady the privilege of raising to the throne the person whom she should fix on for her husband, and her choice fell upon Rotharis, the subject of this article. For the sake of uniting himself with the queen, he repudiated his own wife, whom, however, he promised to maintain in the dignity of a queen. This engagement he did not long regard, but shut her up in an apartment of the palace of Pavia, where she remained five years; when, through the mediation of Clovis II., she was restored to her rank in society. Rotharis had scarcely ascended the throne, when he had to contend with all the power of certain nobles disaffected to his government, which, however, he quelled, and afterwards reigned with equal glory and prosperity at home and abroad. His predecessor had bound himself by a treaty with the exarch of the empire, to restrain himself within certain boundaries; but Rotharis did not conceive himself under any obligation to observe this treaty, and suddenly burst into the province of the Cottian Alps, which he reduced, and then made himself master of all the towns in the Venetian territories. The exarch, at the same time, made an incursion into the Lombard territory, which called away Rotharis from his conquests: an engagement ensued, in which the exarch was totally defeated, and obliged to save the relics of his army by speedy flight. Rotharis likewise penetrated into Liguria, and took Genoa, Alhenga, and other maritime towns, which he pillaged and dismantled, carrying away the inhabitants as prisoners. Rotharis has the high merit of having first given to his nation a code of written laws. In the fifth year of his reign he summoned a general diet of his nobles at Pavia, where, with their consent, he enacted a number of laws, which were made public in an edict issued in 643, consisting of 386 articles. These, though they bear the stamp of a rude age and people, are accounted more judicious than the laws of some other barbaric people. It has been observed, that Rotharis was sufficiently enlightened not only to deride the superstition of witchcraft, but to protect the victims of that reputed crime from popular rage. He also practised religious toleration, and provided in all the cities of his kingdom a bishop for each of the two prevailing persuasions, the Arian and the Catholic. He died in 653, at the age of 47 years, having reigned more than 15 years. Univer. Hist.

ROTHBEIN, in *Ornithology*. See SCOLORAN *Calidris*.

ROTHBURY, in *Geography*, a market-town and parish in Coquetdale ward, in the county of Northumberland, England, is situated  $29\frac{1}{2}$  miles N. by W. from Newcastle, and  $306\frac{1}{2}$  miles N.N.W. from London. In the oldest records, this place is called Robiric, Rathbury, and Routhbiry; and its name has by some been derived from the British word *Rbath*, signifying a cleared spot, or the Gaelic *Rath*, denoting a surety or place of safety; but it is more probable, on account of its Saxon termination, that it was so called from *roth*, red, from the ferruginous appearances around it, where iron mines and ochre abound. Soon after the Conquest, Rothbury, though itself only a member of the barony of Warkworth, appears to have been a large manor, including also those of Thropton and Snitter. King John enfeoffed the barons of Whalton, in this manor, for the payment of one knight's fee. It reverted to the crown, together with Warkworth, by settlement; and was, in 1330, granted to the Percies, and entailed upon their male posterity. The duke of Northumberland is now lord of the manor, but possesses very little freehold property in the town. No remarkable historical event has signalized this place. Previous to the union of England with Scotland, the inhabitants of Rothbury and its vicinity appear to have retained longer than most others the ferocity and lawlessness of the ancient race of borderers. The reformation was late in finding its way hither; and there are yet some traits remaining of the ruder ages, but which are gradually wearing away. A foot-ball play on Shrove-Tuesday, at which all the males above eight years old are required to attend, is one; and the continuance of the custom of bondage-service, in the forest of Rothbury, is another. But this last injurious usage having been abandoned upon the property of the duke of Northumberland, by his grace, it will soon, it is to be hoped, be only remembered by tradition.

According to the parliamentary returns in 1811, the town contains 133 houses, and 750 inhabitants: the parish, however, includes 27 other townships, which comprise 712 houses, and 3732 inhabitants.

Rothbury stands in a sequestered and romantic glen, on the north side of the river Coquet. The town is wide, airy, and tolerably well built, and is much frequented, during the summer season, by valetudinarians, to drink goats' whey; these animals abounding very much amongst the adjacent cliffs and rocks. There is a weekly market, but very indifferently supplied, and it has four fairs in the year. The church is a very ancient structure, dedicated to All-Saints, in the form of a cross, and contains a font of very curious workmanship, and several respectable monuments. Witton or Whitton tower, one of a line of towers, which, in the border-wars, extended from Hepple to Warkworth, a strong ancient building, with the arms of Unfraville on its west side, is now the rector's mansion. The living is worth about 1200*l. per annum*. Here is a bridge of three arches over the Coquet.

On the top of a hill, between this town and Thropton, is a circular intrenchment, with a double ditch and vallum, called Old Rothbury; and not far from it, in a sand-stone rock, is a large cave.

Rothbury-forest is about seven miles from east to west, and four miles from south to north. There is now very little wood upon it, and the whole land is nearly inclosed. It contains mines of lime-stone, coal, iron, and ochre; though, since the wood has disappeared, nothing but coal is dug, and that only to a very limited extent. In that part of the forest, north of the Coquet, and east of Rothbury, near the road leading from Alnwick, are Dibden-wells, the waters

waters of which were formerly held in high estimation, and were much resorted to for the cure of scorbutic eruptions.

Halystone, a small village, about five miles west from Rothbury, is supposed to have been a place of some consequence in the time of the Saxons; for here, according to the venerable Bede, Paulinus baptized, in a copious adjoining spring, called our Lady's well, upwards of 3000 persons. There was also a priory of Benedictine nuns, a few vestiges of which are now in existence.

Harbottle castle, about a mile from Halystone, was once a formidable fortress, but is now in ruins. It was given by William the Conqueror to Robert de Unfraville, lord of Tours and Vian, by a general grant of the lordship of Redefdale, to hold, by defending that country for ever from wolves and enemies, by the same sword which the Conqueror wore when he entered Northumberland. In 1173 it was sacked by the Scots; but in 1296 it was besieged in vain by them. It is now the property of Thomas Clennels, esq., who has built a modern mansion near it.

At Hepple, on the Coquet, about five miles from Rothbury, there was also a strong castle, or tower, of which there are very few remains at present. Cartington castle, two miles north-west from Rothbury, was formerly the seat of the Ratcliffes: the part of it which remains is kept in good repair, and is very strongly built. Here is an asylum for six females of the Roman Catholic religion, who, from their secluded life, are usually called nuns. See *Historical and Descriptive View of the County of Northumberland, &c.*, 2 vols. 8vo. 1811, drawn up by Mr. Mackenzie of Newcastle. *Beauties of England*, vol. vii. Northumberland, by the Rev. Mr. Hodgson.

ROTHEM, a river of Germany, which runs into the Danube, 5 miles above Ulm.

ROTHEMSEE, a lake of Germany, in the principality of Anspach; 6 miles E. of Gerhardsbron.

ROTHENBACH, a town of Germany, in the circle of the Lower Rhine; 30 miles E.S.E. of Francfort on the Maine.—Also, a town of Bavaria, in the bishopric of Bamberg; 2 miles E. of Foreheim.—Also, a town of Bavaria, in the territory of Nuremberg; 3 miles N.W. of Altorf.

ROTHENBURG, a town of Lusatia, on the river Neisse; 14 miles N. of Gorlitz. N. lat.  $51^{\circ} 23'$ . E. long.  $15^{\circ} 2'$ .—Also, a city of Bavaria, capital of a territory, and imperial, near the Tauber, situated on a mountain. The water of the Tauber supplies the town by means of a machine, which raises it to a part called the Klingenturn, and from thence it falls down, forming three fountains in the town. The city is encompassed with ditches and walls, the latter being fortified with towers. It has five churches, and the inhabitants are Lutherans. This is a very ancient place, and it continued imperial till the year 1802, when it was assigned among the indemnities to the elector of Bavaria; 18 miles W. of Anspach. N. lat.  $49^{\circ} 22'$ . E. long.  $10^{\circ} 14'$ .—Also, a town of the duchy of Magdeburg; 40 miles S. of Magdeburg.

ROTHENFELS, a castle giving name to a county, called Konigsegg Rothenfels, and ceded to Bavaria among the indemnities; one mile N.W. of Immerstadt.—Also, a town of the duchy of Wurzburg, on the Maine, the castle of which was demolished by the peasants in the year 1525; 16 miles W.N.W. of Wurzburg.

ROTHENSIRBEN, a town of Silesia, in the principality of Breslau; 8 miles S. of Breslau.

ROTHENSTEIN, a town with a castle, in the duchy of Wurzburg; 8 miles S.S.E. of Königshofen.

ROTHER, a river of England, in Suffex, which runs

into the sea at Rye.—Also, a river in the county of Derby, which runs into the Don, near Rotheram, in Yorkshire.

ROTHER-Beasts, a word used in old statutes, and still in the northern parts of England, for any horned beasts; as oxen, cows, steers, heifers, &c.

Whence *rother-foil*, in Herefordshire, is taken for the dung or foil of such cattle.

ROTHER-Nails, are such as have a very large head, and are used to fasten the rudder-irons in ships. See RUDDER.

ROTHERAM, in *Geography*, a market-town and parish in the upper division of the wapentake of Strafford and Tickhill, West-Riding of Yorkshire, England, is situated near the confluence of the rivers Rother and Don, at the distance of 45 miles S. by W. from the city of York, and 160 miles N.N.W. from London. It is described by Leland as "a meatly large town, with a fare collegiate church," which was founded by Thomas Scott, archbishop of York, and a native of Rotheram, in 1481, for a provost, five priests, a school-master in song, and six choristers, also a school-master in grammar, and another in writing. This establishment was dissolved by king Henry VIII. Camden calls Rotheram "a large footy market town," and not unaptly, for even at the present day it is far from meriting the appellation of handsome or agreeable. The streets are narrow and irregular; and the houses, which are mostly constructed of stone, have a dull and dingy appearance. A considerable trade in coals and other articles is carried on here, by means of the river Don. The market day for corn, cattle, and butcher's meat is on Monday, weekly; and on every alternate Monday is a fair for fat cattle, sheep, and pigs; there are also two annual fairs, on Whit Monday, and the first day of December. Both markets and fairs are well attended; indeed Rotheram is one of the two greatest marts in Yorkshire for fat cattle and sheep. The chief public buildings are the town-hall, the parish-church, and two meeting-houses, one for Independents and another for Methodists. The church, according to Burton, in his "Monasticon Eboracense," was erected in the reign of Edward IV. It is a handsome and spacious edifice, in the early pointed style, and consists of a nave, with two side aisles, a chancel, and a tower at the west end. Annexed to the church is a school-house, for the education of thirty poor children of the parish of Rotheram. The clergyman for the time is governor, and has the nomination of the children; but the trustees of the founder, Thomas Hollis, of London, esq. appoint the master. This institution is managed under very excellent regulations, a copy of which is delivered to the parents of all children admitted to its benefits. In this town is likewise an academical institution, or college, for the education of Protestant dissenters. It is called "The Rotheram Independent Academy," because more immediately connected with the class of religionists called Independents. It was first opened in November, 1795, under the superintendance of the Rev. Dr. Williams, who presided as divinity tutor, and is designed for the education of young men proposing to become Independent clergymen. This academy is supported by voluntary contributions. The building appropriated to it was erected by the late Samuel Walker, esq. and is calculated for the convenient accommodation of sixteen students. The library contains above 1200 volumes, chiefly presented by patrons of the institution; and there is likewise a tolerable collection of philosophical apparatus. The term of study is four years, but the managers have a discretionary power to prolong it if they think proper.

According to the parliamentary returns of 1811, the town of Rotheram alone contained 731 houses, and 2950 inhabitants; and the rest of the parish, including the townships

ships of Brinsworth, Catliffe, Dalton, Orgreave, and Tinsley, 209 houses, and 986 inhabitants.

On the opposite side of the river from Rotheram is the township, or village, of Maxborough, where very extensive iron-works are carried on by Messrs. Walker. At these works cannon of the largest calibre are manufactured, as are also almost every kind of cast-iron articles, with many of wrought-iron, such as bar, sheet, slit, or rod iron. Tin plates, and steel of every description, are likewise made here in great quantities; and the iron bridges at Sunderland and Yarm were cast at these founderies. The coal, and the iron-stone for the blast-furnaces, are chiefly supplied from the mines on the estates of the earl of Effingham, and those of earl Fitzwilliam. These works were commenced, in 1746, by Mr. Samuel Walker, and his brothers Aaron and Jonathan, and have ever since been progressively increasing in extent and importance. In the Methodist meeting-house is a monument in memory of Mr. S. Walker; the epitaph was composed by the celebrated poet, the Rev. William Mason, who was one of his most intimate friends.

The environs of Rotheram are agreeable and picturesque. On an eminence to the eastward of the town stands an elegant mansion, belonging to the Walker family, which, in point of situation, can scarcely be excelled. Aldwark-Hall, the seat of J. S. Foljambe, esq. situated at the distance of four miles from Rotheram, is also remarkable for its fine situation. Near it is the village of Wickersley, noted for its manufacture of grindstones, of which about 5000, of various sizes, are stated to be formed annually, and sent to Sheffield. The other principal seats in the neighbourhood of Rotheram, besides those mentioned, are Thundercliffe Grange, the seat of the earl of Effingham, and Wentworth House, the princely residence of earl Fitzwilliam. The latter house consists of a centre and two wings, extending about 600 feet in length. Many of the apartments are most superb, especially the hall and gallery, the latter of which is supported by beautiful Ionic columns, having intervening niches filled with marble statues. Here, and in other parts of the house, are likewise many paintings; and among others the famous picture of lord Strafford and his secretary. Some fine antiques are preserved in a room called the museum. Wentworth-park comprises upwards of 1500 acres of ground, beautifully diversified with wood, water, and lawn, and is enriched by several ornamental buildings. Among these is a most magnificent mausoleum, erected by the present earl Fitzwilliam, in honour of his uncle, the late marquis of Rockingham. It is constructed of a very fine free-stone, and consists of three divisions; the first is a square Doric basement; the second of the same form, but of the Ionic order; and the third presents a cupola, supported by twelve columns of the same character. Within is an apartment rising into a dome, which rests upon eight pillars, encircling a white marble statue of the marquis in his robes of state, executed by Mr. Nollekens. Beauties of England and Wales, vol. xvi. by J. Bigland.

**ROTHERAM Plough**, in *Agriculture*, a particular sort of plough, which is found very useful, and much employed about the town of that name, in Yorkshire, as well as in many other places in the kingdom. See **PLOUGH**.

**ROTHERHITHE**, in *Geography*, a village and parish in the eastern division of the hundred of Brixton, and county of Surrey, England, is situated on the south bank of the river Thames, at the distance of a mile and a half E. of London bridge. The parish is bounded on the N. and E. by that river, on the S. by the parishes of Bermondsey and Camberwell, on the W. by Horsley-Down, and on the S.E. by the parish of Deptford, in Kent. In this

parish are eleven dock-yards, at some of which ships are built for the service of the East India Company. The manor anciently belonged to the "Abbot of Graces," but was granted, in the reign of Richard II. to the priory of St. Magdalen, Bermondsey. After the suppression of monasteries, it continued annexed to the crown till the reign of Charles I. when it was granted to a gentleman of the name of White, and has since been possessed by various families. This manor has a court-leet and a court-baron. Rotherhithe, not being mentioned in Domesday-book, it seems probable that it was then only a hamlet to Bermondsey. The church was erected in 1715, instead of a former one, which had then become ruinous. It consists of a nave, chancel, and two side aisles, with a square tower, surmounted by a spire at the west end. The living is a rectory in the diocese of Winchester and deanery of Southwark. The only remarkable monument here is that of the Pelew prince, Lee Boo, who died of the small-pox December 29th, 1784, in the 20th year of his age. This young man was the son of Abba Thulle, king of the island of Goo-roo-raa, and came to England with captain Wilson, whose ship, the Antelope, was wrecked off that island 9th August, 1783, on which occasion the natives treated the crew with the utmost humanity and kindness. In this parish is a free-school, at which about 30 boys and 20 girls are clothed and educated.

According to the parliamentary returns of 1811, Rotherhithe parish contains 2719 houses, and 12,114 inhabitants. The History and Antiquities of the County of Surrey, by the Rev. Owen Manning, continued by William Bray, esq. folio, vol. i. Antiquities of Surrey, by N. Salmon, L. L. B. Lond. 8vo. 1736. Aubrey's Natural History and Antiquities of Surrey, vol. v. 8vo. Lond. 1719. Lysons's Environs of London. vol. i. 4to. Lond. 1796. And Supplement to the latter, 1813.

**ROTHERSAY**, or **ROSAV**, a royal borough-town and parish in the county and isle of Bute, Scotland, is situated on the bank of a fine bay, at the N.W. side of the island. The ancient Gaelic and patronimic name of this parish is Cilla-bhruic, which signifies the church dedicated to St. Broke. The town is yet called, in the Gaelic language, Bailea-Mhoide, or the town where the courts of justice are held. Rotherfay is undoubtedly of high antiquity; but it does not seem to have been constituted a royal borough till the year 1400, when king Robert III., who was then resident at the castle, raised it to that dignity. At that period it was a considerable town, but in succeeding years it declined greatly both in extent and population, as was apparent in the early part of the last century, by the number of ruinous houses, and foundations of others, which were then visible. About fifty years ago, indeed, it was reduced to the condition of a mean village, possessing only one decked vessel of inconsiderable burthen. Under the auspices of the late earl of Bute, however, the industry and emulation of the inhabitants began to revive, and the town has again advanced to a state of comparative prosperity and opulence. Even so early as 1790, the inhabitants had accumulated shipping to the amount of 4246 tons, and it is believed the estimate of tonnage is now nearly doubled. This change has been principally effected by the encouragement given to the herring-fisheries, in which the inhabitants of Rotherfay have about 100 small vessels employed annually; but in part it is likewise to be attributed to the establishment of some cotton-mills in the immediate vicinity. Rotherfay, as a royal borough, unites with Cambletown, Irvine, Inverary, and Ayr, in the election of a representative to the great council of the nation. It is the seat of the county courts of justice; and has the honour of giving the title

-title of a Scottish dukedom to the heir apparent of the British throne.

The castle of Rothefay is now a mere ruin, and is so completely enveloped with ivy, that only small portions of its walls are discernible to the eye. It was erected at different periods; part of it, forming the present entrance, by king Robert III., and the remainder at a much more remote date. The latter division is quite circular, and is strengthened by projecting round towers. This castle, in remote times, was the scene of several events of military note in Scottish history. According to Torfæus, Hufbec, grandson of Somerled, was killed in an attack on a castle in Bute, most probably of this. In 1263, Haco, king of Norway, obtained forcible possession of it, and of the whole island; and in 1334 it was seized by Edward Baliol, because its then owner, the high steward of Scotland, was related to the Bruces, and was next heir to the throne. The year following, the island was invaded by the English under lord Darcy, and given up to plunder; which so exasperated the natives, that, in conjunction with those of Arran, they made an attack upon the castle soon after lord Darcy left it, and succeeded in regaining possession of it. Subsequent to this period it became a royal residence. King Robert II. and III. lived in it for a considerable time; and it would appear that much attention was bestowed on it, for in the reign of James V. we find that one of the articles of accusation exhibited against sir James Hamilton, was his not accounting for three thousand crowns destined for the "reform of the castle and palace of Rosfay." In 1544, the earl of Lennox, assisted by the English, made himself master of this place; after which it became the principal residence of the Stuarts, ancestors of the present family of Bute, and continued so till the year 1685, when it was burnt by the duke of Argyll. The earl of Bute, however, yet ranks among his titles that of hereditary keeper of this palace.

The parish of Rothefay extends about ten miles in length, and from three to four in breadth. In the time of episcopacy, it was within the diocese of the Isles, and on the establishment of Presbyterianism, was included in the presbytery of Irvine, or Cuninghame, and the synod of Glasgow and Ayr. In 1639, however, it was disjoined from that presbytery and synod, and annexed to the presbytery of Denoon, and synod of Argyle, to which it continues united. According to the parliamentary census of 1811, this parish contained 702 houses, and 4970 inhabitants, of whom 3544 are resident within the borough. The Statistical Account of Scotland, by Sir John Sinclair, bart. vol. 1. 8vo. 1791. Pennant's Tour in Scotland, &c. 4to. vol. 1. Lond. 1776. Beauties of Scotland, vol. v. 8vo. 1808. Carlisle's Topographical Dictionary of Scotland, 2 vols. 4to. 1813.

ROTHERWASSER, a river of Saxony, which runs into the Elbe, about three miles below Pirna.

ROTHHAUSEN, a town of Germany, in the county of Henneberg; 8 miles S. of Meinungen.

ROTHHEIM, a town of the duchy of Wurzburg; 5 miles N.E. of Aub.

ROTHIA, in *Botany*, received its name from Schreber, in honour of Dr. Albert William Roth, a physician of the duchy of Bremen, born in 1755; whose *Flora Germanica*, though as yet unfinished, his *Catalecta Botanica*, and various other works, have procured him a distinguished rank amongst European botanists.—Schreb. Gen. 531. Willd. v. 3. 1611. Mart. Mill. Dict. v. 4. Ait. Hort. v. 463. Lamarck Illustr. t. 667. Gært. t. 174. v. 1. 103.—Class and order, *Syngenesia Poly-*

*gamia-aqualis*. Nat. Ord. *Compositæ semisfosculosa*, Linnæ. *Cichoraceæ*, Juss.

Gen. Ch. *Common Calyx* rounded, finely villous; of about seven equal, linear, acute scales. *Cor.* compound, imbricated, uniform, of numerous equal florets, all perfect, whose partial corolla is of one petal, ligulate, linear, abrupt, with five teeth. *Stam.* Filaments in each floret five, capillary, very short; anthers united into a cylindrical tube. *Pist.* Germen in each floret ovate; style thread-shaped, the length of the stamens; stigmas two, reflexed. *Peric.* none, the calyx closing over the seeds, which are solitary in each floret; those of the disk cylindrical, somewhat turbinate, striated, with sessile capillary down, feathery in its lower part; those of the radius cylindrical, striated, enveloped in scales of the receptacle, but destitute of down. *Recept.* flat; hairy in the disk; chaffy at the radius; the chaffy scales in several rows, linear, channelled, erect, rather acute, tubular at the base, the outermost equal in length to the calyx, the inner ones gradually shorter.

Eff. Ch. Receptacle hairy; chaffy in the circumference. Calyx of many equal scales. Seed-down hairy, sessile in the disk; none in the radius.

Obf. This genus, as every body observes, is very near *Andryala*, and we greatly fear ought not to be separated from it. Dr. Roth at first named it, after a friend of his, *Voigtia*, in Roemer and Ullers' Magazine, Fasc. 10. 17. What Gærtner has delineated and described for *Andryala*, v. 2. 361. t. 158, is now made a species of *Rothia*; to which circumstance however he does not advert at p. 371 of the same volume, where *Rothia* is described; neither does Roth, in his original description of this genus, seem to have had *Andryala* at all in his contemplation, or he would surely have contrasted their essential characters. In fact the genus of *Andryala* itself depends upon two of the species now called *Rothia*, with which the third indubitably accords. If *A. lanata* of Linnæus constituted a distinct genus, the name of *Andryala* might remain with it; but there is much reason to believe this plant ought to be referred to *Hieracium*, the hairiness of its receptacle being uncertain or variable. *A. cheiranthifolia* and *ragusina* have so precisely the habit of *Rothia*, that we can hardly allow them to be separated from it by any technical characters that we can discern. In this difficulty we shall here give the species of *Rothia* as we find them; only premising that, by any thing here said, we mean not to invalidate Dr. Roth's claim to be commemorated by some certain and immutable genus, to which his high botanical merits richly entitle him.

1. *R. andryaloides*. *Andryaline Rothia*. Gært. v. 2. 371. Roth. Catal. n. 1. Willd. n. 1. (*Voigtia tomentosa*; Roth in Roem. and Ull. Mag. fasc. 9. 17.)—Stem much branched from the very base. Leaves downy, ovato-lanceolate, clasping the stem, nearly entire.—Native of Spain. Root annual, branched, somewhat woody. Stem twelve or eighteen inches high, erect, brown, downy; its branches alternate, widely spreading. Leaves alternate, distant, recurved, rather wavy, downy, and hoary. Flower-stalks axillary and terminal, solitary, nearly twice as long as the leaves, naked, erect, single-flowered, extremely downy. Bractea solitary under each flower, lanceolate, very downy, scarcely longer than the calyx, which is also downy and whitish; contracted and globose before the flower opens, but afterwards lax, consisting of from five to seven scales. Corolla yellow; the florets of the circumference purplish at the back. The outer row of scales of the receptacle is exactly like the calyx; the rest gradually smaller, downy on the outside. The flowers are open before noon only. The

The whole herb has straight, prominent, capitate hairs, intermixed with its downy pubescence. *Roth.*

2. *R. cheiranthifolia*. Stock-leaved *Rothia*. *Roth.* Catal. n. 2. Willd. n. 2. Ait. n. 2. (*Andryala sinuata*; Linn. Sp. Pl. 1137. *A. integrifolia* β; Syst. Nat. ed. 12. v. 2. 525.)—Stem erect, corymbose. Leaves finely woolly, lanceolate, sinuated, or deeply toothed; the uppermost sessile, ovate, taper-pointed, entire. Native of Spain and the south of France, flowering there in May. It is marked in Hort. Kew. as a hardy annual, flowering in July and August. *Herb* milky, clothed with dense, white, woolly down, intermixed in the upper part with copious, prominent, capitate, tawny hairs, giving it a reddish hue, especially when old. *Stem* twelve or eighteen inches high; branched above, at first corymbose, then racemose. *Leaves* sessile, alternate, rather distant, obtuse; the lower ones about a finger's length, with short, triangular, distant teeth, and intermediate sinuses; the uppermost gradually smaller and entire. *Flower-stalks* naked, or with here and there a linear *bractea*. *Calyx* of from three to five scales. Outer scales of the *receptacle* like the calyx in structure, but rather longer, very downy at the back; inner ones shorter, smooth, and more membranous. *Corolla* of a golden yellow in every part.—We cannot help suspecting that what Dr. Roth thus describes as the outer scales of the *receptacle*, do in fact belong to the *calyx*, which appears to us composed of a row of very numerous equal woolly scales, furrounded with a few shorter external ones, as usual in many of this tribe.

3. *R. runcinata*. Hoary *Rothia*. *Roth.* Catal. n. 3. Willd. n. 3. Ait. n. 2. (*Andryala integrifolia*; Linn. Sp. Pl. 1136. Syst. Nat. ed. 12. v. 2. 525. α. *Sonchus lanatus*; Dalech. Hist. v. 2. 1116.)—Stem erect, corymbose. Leaves downy; the lower ones oblong, runcinate; upper lanceolate, slightly toothed. Flower-stalks villous, glandular.—Native of the south of Europe. Biennial, twice as large as the foregoing, and varying much in luxuriance. The lower *leaves* are stalked. Whole *herb* clothed with fine, dense, velvet-like pubescence, very thick and woolly about the *calyx*, which is moreover beset with long golden hairs. *Roth*, very paradoxically, describes the *calyx* as consisting of only one or two leaflets, or scales, reckoning as scales of the *receptacle* what all the world, surely, would call a *calyx*. This, therefore, is only a difference of words, and appears still further to invalidate the distinction between *Rothia* and *Andryala*. These plants, in reality, require to be all examined and compared, in a living state, by some botanist accustomed to consider genera on a large scale, and who is particularly acquainted with syngeneisous plants. We do not profess to be, at present, furnished with materials for the purpose.

ΡΟΤΙΑ, in *Geography*, a town of the island of St. Vincent, in York bay. N. lat. 13° 7'. W. long. 61° 16'.

ROTHLA, a town of Bavaria, in the territory of Rothenburg; 8 miles N. of Rothenburg.

ROTHMUNSTER, a princely abbey of Germany, on the Neckar, given as an indemnity, in the year 1802, to the prince of Hohenlohe; 2 miles S. of Rothweil.

ROTHWEIL, a town of Wurtemberg, situated on the Neckar, being a very ancient imperial town, and which the emperors Charles IV. and Wenceslaus engaged to maintain as such. It is chiefly remarkable for its imperial tribunal, the first traces of which are to be found in the provincial court of Swabia, which seems to have originated in the time of the emperor Louis of Bavaria, and, till the middle of the 15th century, was sometimes called the provincial court of the emperor, and sometimes the imperial tribune of Roth-

weil. In the year 1802 it was given to the duke of Wurtemberg; 44 miles S.S.W. of Stuttgart. N. lat. 48° 7'. E. long. 8° 34'.

ROTHWELL, called also ROWELL, a town and parish in the hundred of Rothwell, and county of Northampton, England, is situated 4 miles N.W. by W. from the town of Kettering, and 78 miles N.W. by N. from London. This place is said to derive its name from two remarkable springs in the vicinity, the water of one of which is of a petrifying quality, and in the other are frequently found numerous small bones, conjectured to be those of frogs. Here was a small priory of Augustine nuns, dedicated to St. John Baptist, and which was probably founded by the Clare family, whose successors in the manor appear, upon record, as its patrons. Rothwell was formerly a considerable market-town, but the market has been long discontinued. The market-house is worthy of attention, from the style of the building. It was begun by sir Thomas Tresham, but never completed, owing to his death, which happened in the third year of James I. His son and successor, Francis Tresham, was providentially the instrument of the discovery of the gunpowder-plot, by sending a letter to lord Monteagle, who had married Mr. Tresham's sister, and thus led to the detection of the conspiracy.

In the church are several monumental memorials of the Tresham family, and others for different persons. Rothwell has an annual fair, held on Trinity-Monday. According to the returns to parliament in 1811, the parish contains 330 houses, and 1451 inhabitants.

In the hundred of Rothwell, at Great Oxendon, is a remarkable echo in the belfry of the church-tower. To a person standing at the distance of 673 feet, on the western part of the elevated ground on which the church is built, this echo returns distinctly thirteen syllables. An echo, but not to an equal extent, is obtainable from the top of an adjacent hill to the south; but scarcely any exists on the eastern or northern sides of the tower. But it is said, that the effect has lately been considerably diminished, by alterations which have been made in the belfry-windows.

Braybrooke church, between Oxendon and Rothwell, exhibits a very curious and highly decorated monument, erected for sir Nicholas Griffin, knight, who died in 1509. It displays an assemblage of pedestals, shields, crests, and other ornaments, very characteristic of the age of queen Elizabeth.

Kelmarsh-hall, on the one side of Rothwell, and Rushton-hall, on the other, are noble family mansions; and the latter in particular is very beautifully situated.

Robert Talbot, one of our early English antiquaries, who flourished about 1546, was a native of Thorpe Malton, a village between Rothwell and Kettering. He was the friend and associate of Leland, and both Camden and Burton seem to have made considerable use of his annotations on the Itinerary of Antoninus. History, &c. of Northamptonshire, by Bridges and Whalley, 2 vols. folio. A new edition, with large additions and corrections, of this work, is now preparing by Mr. George Baker of Northamptonshire.

ROTHWENDS DORF, a town of Saxony, in the margraviate of Meissen; 3 miles S. of Pirna.

ROTIME, a town of Fez, near the Atlantic.

ROTKNUSSEL, in *Ornithology*, a name by which the Germans call the *gallinula melampus* of Gessner. It is a bird somewhat approaching to the snipe-kind; its back is brown, with a slight admixture of reddish, and some spots of a dusky colour; its wings are variegated with black and white, and

its beak and legs are black. It is common in many parts of Germany. See *GLAREOLA Nævia*.

ROTLESREUT, in *Geography*, a town of Germany, in the principality of Culmbach; 5 miles S.E. of Culmbach.

ROTMEINSDORF, a town of the duchy of Wurzburg; 2 miles E. of Ebern.

ROTNEBY, or RONNEBY, a sea-port town of Sweden, near a river of the same name, which runs into the Baltic. It has some trade, a harbour, medicinal springs, and several manufactures. The inhabitants are free of Carlscrona; 9 miles W. of it.

ROTOLO, an Egyptian weight of twelve ounces, each ounce confisting of twelve drachms, and each drachm of sixteen carats. See *ROTOLO*.

ROTONDO, ROTUNDO, in *Architecture*, a popular term for any building that is round both within and without, whether it be a church, hall, a saloon, a vestibule, or the like.

The most celebrated rotondo of antiquity is the Pantheon at Rome, dedicated to Cybele, and all the gods, by Agrippa, son-in-law of Augustus; but since consecrated by pope Boniface IV. to the Virgin, and all the saints, under the title of Sta. Maria della Rotondo.

The chapel of the Escorial, which is the burying-place of the kings of Spain, is also a rotondo; and, in imitation of that of Rome, is also called Pantheon.

ROTONDO, in *Geography*, a town of Naples, in the province of Basilicata; 6 miles S.S.E. of Turfi.

ROTRON, JOHN DE, in *Biography*, a French dramatic writer, was born, in 1609, of an ancient family at Dreux. He distinguished himself by a great facility in composing dramatic pieces, both in tragedy and comedy. In this line of literature he was so far superior to his predecessors, that he is denominated by Voltaire "the founder of the theatre." He was patronized by cardinal Richelieu, and Corneille used to call him his father. He was always a needy man, and wrote most of his pieces under the pressure of immediate necessity, so that he never had an opportunity of giving a finish to them. At length, however, he was enabled to purchase the office of lieutenant-particular of his native place, where he constantly resided. A pestilential disorder breaking out, and making great ravages at Dreux, he was intreated by his brother to quit that town, and come to Paris; but his reply shewed that he was resolved to remain on the spot where his duty placed him. In one of his letters he said, "At the moment I am writing, the bell is tolling for the twenty-second death this day: my turn will come when it pleases God." He died in a very short time after this, in the 41st year of his age. Of his numerous plays, the best are "Chofroes," "Antigone," and "Wenceslaus." The latter was revived by Marmontel, and Voltaire speaks of several parts of it in the highest terms.

ROTSCHOWALM, in *Geography*, a sea-port of Russia, in the government of Viborg, situated on the north coast of the gulf of Finland, on the borders of Sweden, formed by several islands, fortified with forts and redoubts.

ROTSCHWENTZEL, in *Ornithology*, the name of a bird described by Gesner, and some other authors, and seeming to be the same with our *ruicilla*, or red-start. See *MOTACILLA Phœnicurus*.

ROTSIMPA, in *Ichthyology*, a name given by the Swedes to a species of cottus, called by Jonston and Schonveldt *scorpius marinus*. It is different from the scorpena of the generality of writers, and is of the cottus kind. It is distinguished by Artedi under the name of the *smooth cottus*,

with many thorns upon the head, and with the upper jaw somewhat longer than the under one. See *COTTUS Scorpius*.

ROTSUSTA, in *Geography*, a river of Walachia, which runs into the Podrus, 5 miles N.W. of Strehaja.

ROTTBOLLIA, in *Botany*, so named by the younger Linnæus, after Dr. Christian Friis Rottböll, Professor of Botany, as well as of Anatomy, in the university of Copenhagen, who died in 1797, aged 70. He is particularly distinguished by his descriptions and figures of new or rare plants, a thin folio, published in 1773, with 21 very neat and accurate plates. As this volume contains only plants of the order of *Calamariæ*, it is usually quoted *Rottboll's Gramina*, or Grasses, though that appellation is not precisely correct. The same writer has published several botanical treatises besides, either in the form of university essays, or in the Medical Transactions of Copenhagen.—Linn. fil. Nov. Graminum Genera, 23, with a figure. Suppl. 13. Schreb. 721. Willd. Sp. Pl. v. 1. 463. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 1. 175. Sm. Fl. Brit. 151. Prodr. Fl. Græc. Sibth. v. 1. 71. Brown Prodr. Nov. Holl. v. 1. 206. Juss. 31. Lamarek Illustr. t. 48.—Clafs and order, *Triandria Digynia*. Nat. Ord. *Gramina*, Linn. Juss.

Gen. Ch. *Common Receptacle* cylindrical, thread-shaped, jointed, with an oblong excavation on one or two sides of each joint, at the bottom. *Cal.* Glume lateral, fixed, simple or divided, closing the hollows of each joint, and containing one or two florets. *Cor.* Glume concealed by the calyx, of one or two membranous unawned valves. *Stam.* (in each floret) Filaments three, capillary; anthers linear, forked at each end, hanging out of the floret. *Pist.* (in one floret only of each joint) Germen oblong, abrupt, convex at one side, concave at the other; styles two, capillary; stigmas feathery, prominent. *Peric.* none, except the hollow of each finally separated joint, closed with the calyx. *Seed* solitary, the shape of the germen.

Ess. Ch. Calyx fixed, nearly single-flowered, simple or divided. Flowers alternate, on a jointed common stalk.

Obs. The genera which our learned friend Mr. Brown has separated from *Rottbollia* will be found mentioned under the articles *HEMARTHRIA*, *LEPTURUS*, *OPHIURUS*, and *MICROCHLOA*. The last we conceive to be the most distinct. We shall here take the genus *Rottbollia* as it stands in Linnæus and Willdenow, and have drawn up the generic character accordingly.

1. *R. incurvata*. See Hard-grafs. Linn. Suppl. 114. Willd. n. 1. Ait. n. 1. Fl. Brit. n. 1. Fl. Græc. t. 91. Engl. Bot. t. 760. Knapp. Gram. t. 103. Pl. Dan. t. 938. (*Aegilops incurvata*; Linn. Sp. Pl. 1490.)—Spike round, awl-shaped, incurved. Glume of the calyx awl-shaped, close-pressed, deeply divided. Stipula very short, abrupt.—Native of the sandy sea-coasts of Europe. A small annual grass, flowering in August. The root consists of numerous long capillary fibres. Stems numerous, decumbent at the base, from three inches to a foot long, branched, jointed, leafy, round, slender, very smooth. Leaves linear, acute, narrow, rough on the upper surface and edges; their sheaths a little swelling, smooth, striated, shorter than the leaves, each crowned with a short blunt stipula. Spikes solitary at the end of each branch, rigid, long and slender, more or less curved. Calyx spreading whilst in full bloom. Florets solitary, perfect, all fertile.

2. *R. filiformis*. Thread-shaped Hard-grafs. Roth. Catal. v. 1. 21. Nardus gangitis; Herb. Linn. (*Gramen junceum nodosum minimum capillare*; Barel. Ic. t. 117. f. 1.)—Spike thread-shaped, slightly compressed, erect.

erect. Glume of the calyx sword-shaped, deeply divided. Stipula elongated, lanceolate, obtuse, jagged.—Native of the south of Europe. Much more slender than the former, with a purplish stem, and smaller, rougher, channelled leaves. Florets more crowded together. This is certainly what Linnæus had in his herbarium for *Nardus gangetis*, when he described that plant in his Sp. Pl. ed. 1. 53, though the mark of a cross indicates that he had some doubts concerning it. Those doubts arose from the synonyms quoted in the Sp. Pl. which have nothing to do with the grass before us. Their history may be found in Transf. of Linn. Soc. v. 1. 116.

3. *R. cylindrica*. Stout Hard-grafs. Willd. n. 3. (Gramen loliaceum junceum majus; Barel. Ic. t. 5. G. loliaceum, spicis articulosis erectis; Mont. Gram. 43. f. 28. G. myuros, &c.; Bocc. Mus. 70. t. 59.)—Spike round, awl-shaped, slightly curved. Glume of the calyx undivided.—Native of the south of Europe. This appears to be of a stouter habit than even the first species, but we know nothing of it, except from the authors quoted. Monti says it differs from *R. incurvata* in having the glume of the calyx undivided.

4. *R. Thomæa*. Mouse-tail Hard-grafs. Willd. n. 4. Roxb. Corom. v. 2. 17. t. 132. (*R. pilosa*; Willd. n. 7. *Nardus Thomæa*; Linn. Suppl. 105.)—Spike linear, compressed, nearly straight. Florets imbricated, in two rows.—Gathered by Koenig on the mountain of St. Thomas in Tranquebar. A small, glaucous, densely tufted grass, whose leaves are fringed with long hairs. Spikes solitary on each stem; their common stalk zigzag at each of the flat sides of the spike, but not perceptibly jointed. Florets imbricated closely, in an alternate order, along each edge of the spike. Glume of the calyx keeled, undivided, a little recurved at the point.

5. *R. repens*. Creeping Hard-grafs. Forst. Prodr. 9. Willd. n. 5. (*Lepturus repens*; Brown Prodr. Nov. Holl. v. 1. 207.)—Spike round, awl-shaped. Glume of the calyx undivided. Sheath of the leaves bearded at the top. Root creeping.—Native of the South Sea islands, and the tropical part of New Holland, on sandy sea-shores. Branches ascending. Leaves imperfectly two-ranked, straight, linear, rather involute; their sheaths bearded, with scarcely any visible stipula. Spike thread-shaped, acute, beardless; its joints separable. Glumes of the calyx pointed, longer than their corresponding joints. Brown.

6. *R. levis*. Smooth Hard-grafs. Retz. Obf. fasc. 3. 11. Willd. n. 6.—Spike cylindrical. Joints two-flowered. Glumes of the calyx oblong, obtuse, undivided, very smooth, the length of the joint.—Native of Tranquebar. Roots apparently perennial, with strong fibres. Stems ascending, a foot or more in height, scarcely branched, leafy. Leaves densely tufted at the root, short, broad and flat, smooth; their sheaths densely bearded, without any membranous stipula: stem-leaves short, distant, with long sheaths. Spikes terminal, solitary, erect, three or four inches long, pale, smooth, each joint furrowed, with two lateral, not quite opposite, hollows. Glume of the calyx very smooth and even like ivory, with an obtuse, oblique, greenish point, and a little furrowed at the very base.

7. *R. compressa*. Flat-spiked Hard-grafs. Linn. Suppl. 114. Willd. n. 8. Retz. Obf. fasc. 3. 12. Roxb. Corom. v. 2. 30. t. 156. (*Hemarthria compressa*; Brown Prodr. Nov. Holl. v. 1. 207.)—Spike compressed, awl-shaped, incompletely jointed. Joints two-flowered. Outer glume of the calyx undivided; the points of all the glumes

straight.—Native of the East Indies, China, and New South Wales, about ponds. Stems compressed, leafy. Leaves smooth, naked, with compressed sheaths. A stalked tuft of spikes, accompanied by a leafy involucre, springs from the upper sheaths. Calyx of two valves; one of them internal.

8. *R. uncinata*. Hooked Hard-grafs. (*Hemarthria uncinata*; Brown Prodr. Nov. Holl. v. 1. 207.)—Spike compressed, awl-shaped, incompletely jointed. Joints two-flowered. Outer glume of the calyx undivided; the point of the inner one hooked.—Gathered by Mr. Brown in the island of Van Diemen.

9. *R. hirsuta*. Great Hairy-spiked Hard-grafs. Vahl. Symb. fasc. 1. 11. Willd. n. 9. (*Triticum ægilopoides*; Forsk. Ægypt-Arab. 26.)—Spike awl-shaped, very hairy. Calyx of the perfect florets spreading; of the male ones close-pressed. Stem angular in the upper part.—Native of Egypt; not unfrequent about Alexandria, flowering in March. We have specimens from Dr. Delile, who informs us that a figure of this grass is delineated for the great work, descriptive of Egypt, part of which has already appeared at Paris. The stem is branched, rigid, about two feet high, leafy, jointed, the upper joints angular, being flattened at one side, striated, a little roughish. Leaves involute, rigid; their sheaths smooth, strongly furrowed, crowned with a tuft of hairs; the upper ones somewhat inflated. Spike solitary, partly enveloped in the uppermost sheath, about three inches long, rather compressed. Glumes lanceolate, taper-pointed, emarginate, clothed externally with copious, long, white hairs.

10. *R. Cymbachne*. Boat-valved Hard-grafs. Willd. n. 10. (*Cymbachne ciliata*; Retz. Obf. fasc. 6. 36.)—Spikes in pairs, flowering at one side only. Calyx of the perfect florets with an inner, boat-like glume. Leaves fringed at the base.—Found by Koenig in Bengal. A slender grass, a foot high, with several, simple or branched, stems; the latter bearing one leaf, the others leafless. Leaves short, thin, fringed at the margin, above the sheath, with long, white, separate hairs; sheath abrupt, pale-brown at the summit, fringed. Spikes terminal, in pairs, linear, an inch and a half long, some consisting of perfect, the others of female, flowers. Common stalk linear, membranous, flat at the back, with three longitudinal furrows; zigzag, with alternate hollows, in front. Calyx of the perfect flowers of two valves, single-flowered, both of them parallel and exposed to view, close-pressed to the common stalk, or receptacle; the outermost valve linear, obtuse, fringed at the back; innermost half-ovate, acute, boat-shaped, greatly compressed, striated, coloured, fringed at the back, inclosing the corolla. Anthers and stigmas black. Female flowers with a single-valved, close-pressed, ovate, fringed calyx, slightly cloven at the point. Corolla and filaments wanting. Stigmas longer than in the former. Retzius.

11. *R. Coelorachis*. Hollow-stalked Hard-grafs. Forst. Prodr. 9. Willd. n. 11.—“Spike round, flowering at one side only. Florets in pairs; one of them stalked. Calyx of two valves.”—Native of the island of Lanna. We have seen no specimen. Mr. Brown mentions this as one of the few certain *Rottböllia*, according to his own strict limitation of the genus. We presume, from the name, that Forster had originally considered this plant as constituting a distinct genus; and that he named it in allusion to the hollows of the common receptacle; which, nevertheless, are proper to *Rottböllia*.

12. *R. dimidiata*. Half-spiked Hard-grafs. Linn. Suppl. 114, excluding the synonym. Willd. n. 12.—Spikes compressed,

compressed, flowering at one side; striated with undulating lines at the other. Flowers two to each joint, one rather above the other, with short abrupt scales at their base.—Native of the East Indies, and of the Brasils, in sandy ground. Whether Thunberg's Cape plant be the same, we are not certain, there being some confusion between our *Rottböllia* and the *Panicum dimidiatum* of Linnæus; which latter we have never seen, but Koenig and Retzius insisted on their being two very different things. *R. dimidiata* is a stout, branched, smooth grass, with very broad, obtuse, spreading leaves, whose sheaths, like the stem, are very much compressed. Spikes several, on solitary or clustered, simple, axillary and terminal, stalks, two or three inches long, about their own length. Each spike is tapering, stout, jointed, curiously striated at the back, with alternately curved and recurved lines; bearing, at the opposite side, on each joint, two angular flowers, one elevated above the other, and each accompanied by a short scale at the base. The structure of the flowers we have not been able to examine.

13. *R. exaltata*. Tall Hard-grass. Linn. Suppl. 114. Willd. n. 13. Brown Prodr. n. 1. Roxb. Corom. v. 2. 30. t. 157. (*Stegofia cochinchinensis*; Loureir. Cochinch. 51, on the authority of a specimen from the author, in the Banksian herbarium.)—Spike round, flowering on every side, beardless. Glumes obtuse, rough as well as the common receptacle. Leaves and their sheaths hairy.—Native of the East Indies, and of Cochinchina. A tall grass, with a solid stem. Sheaths of the leaves furrowed, besprinkled with elevated points, each bearing a bristle. Spikes solitary, lateral, four or five inches long.

14. *R. formosa*. Silky Hard-grass. Brown n. 2.—“Spike round, flowering on every side; its joints, as well as the outer glumes of the perfect flowers, silky; those of the neuter ones smoothish and empty.”—Gathered by Mr. Brown in the tropical part of New Holland.

15. *R. perforata*. Perforated Hard-grass. Roxb. Corom. v. 2. 43. t. 182.—Spike round, flowering on every side, beardless. Glumes obtuse, smooth. Common receptacle perforated in each joint, between the opposite flowers. Leaves smooth. Sheaths woolly at their summit.—Native of low rich pasture-ground on the coast of Coromandel, but rare. Root fibrous. Stems several, about two feet high, erect, round, jointed, solid, slender, smooth, leafy. Leaves small, narrow, smooth, except at their edges. Sheaths very woolly at the summit within, which wooliness extends a little way up the leaf. Spikes solitary, stalked, terminal and axillary, slender, erect, four or five inches long. Flowers two to each of the lower joints, opposite; one to each of the upper ones; sometimes all perfect; sometimes many of them have *stamens* only. This, like most of the other species, is a coarse grass, not eaten by cattle.

16. *R. corymbosa*. Corymbose Hard-grass. Linn. Suppl. 114. Willd. n. 14. Roxb. Corom. v. 2. 42. t. 181. (*R. punctata*; Retz. Obs. fasc. 3. 12. *Ægilops exaltata*; Linn. Mant. 575. Retz. Obs. fasc. 2. 27. *Ophiurus corymbosa*; Brown Prodr. Nov. Holl. v. 1. 207.)—Spikes aggregate, thread-shaped, smooth. Glume of the calyx ovate, obtuse, undivided, with reticulated depressions.—Native of ditches on the coast of Malabar, as well as of the tropical region of New Holland. The stem is tall, round, leafy, finely striated, smooth. Leaves flat, with long smooth sheaths. Spikes purplish, many together, slender, in tufts, on simple or compound, smooth, cylindrical stalks, from the sheaths of the short uppermost leaves. Glume of each calyx the length of the joint, a little spreading, at

least in the dry specimen, and curiously reticulated at the outside.

17. *R. digitata*. Finger-spiked Hard-grass. Sm. Fl. Græc. Sibth. v. 1. 73. t. 92.—Spikes terminal, clustered. Receptacle angular, rough. Flowers partly stalked. Glumes keeled, taper-pointed. Sheaths of the leaves hairy. Gathered by Dr. Sibthorp in the low country about the base of the Bithynian Olympus. This is a large grass, three feet high, with all the appearance of being perennial. Stem branched, leafy, round, smooth. Leaves a foot or more in length, moderately spreading, flat, acute, rather glaucous, with a pale central rib; their upper side rough, and often hairy; their sheaths long, close, ribbed, dotted and hairy. Stipula of a few short hairs. Spikes several, from nine to twelve inches long, erect, forming an oblong tuft at the top of the stem; rarely solitary. Receptacle, or common stalk, of each zigzag, angular, rough-edged, every joint accompanied at its concave smooth side by two flowers, one sessile, the other on a stout, angular, club-like stalk, half the length of the corresponding joint. Calyx of two unequal, awl-shaped, rough-keeled valves; that of the stalked flower containing two *florets*, one of which is male; that of the sessile flower only a solitary *floret*, sometimes perfect, sometimes furnished merely with *stamens*. Corolla in all the *florets* of two pellucid white glumes, shorter than the calyx. Anthers and stigmas yellow.

18. *R. muricata*. Prickly Hard-grass. Retz. Obs. fasc. 3. 12. Willd. n. 15. (*Ægilops muricata*; ib. fasc. 2. 27.)—“Spikes round, several together, on long stalks. Calyx fringed with prickles; the neuter ones cloven.”—Found in the East Indies, by Koenig.—Stems angular, leafy. Sheaths of the leaves fringed. Spikes axillary, two or three together, thicker than in *R. exaltata*, each on a long stalk. Calyx slightly downy, fringed with marginal prickles.

19. *R. sanguinea*. Red-flowered Hard-grass. Retz. Obs. fasc. 3. 25. Willd. n. 16.—Spikes axillary, alternate, stalked, approximated. Corolla awned at the base.—Native of China.—Stem semi-cylindrical, jointed, leafy; the upper joints invested with dilated, hood-like sheaths, from each of which springs a solitary spike, on a long stalk, the latter concealed by the sheath. Spikes thread-shaped. Flowers alternate. Corolla red, with a long awn from its base. Retzius's description of a *bractea*, as well as of the parts of the flower, is not clear to us without a specimen. He says this grass has entirely the aspect of an *Andropogon*.

*R. monandra*, Cavan. Ic. v. 1. 27. t. 39. f. 1. Læccion. 52, seems rather a species of *Nardus*, and is, we believe, the *N. aristata* of Linnæus, under which name it was sent to Mr. Davall, by signor Molineri, from Piedmont. See NARDUS, n. 2, where Cavanilles may safely be cited.

ROTTE, in Geography. See ROTAI.  
ROTTELN, a town of the duchy of Baden; five miles N.N.E. of Bäle.

ROTTEN STONE, in Mineralogy, a decomposed stone, used for polishing. See TRIPOLI.

ROTTENBACH, in Geography, a town of Bavaria, in the territory of Nuremberg; three miles S.S.W. of Lanf.

ROTTENBERG, a town of Bavaria; 14 miles N.N.W. of Landshut.

ROTTENDEAN, a village of England, in Suffex, very near the sea, and frequented for sea-bathing; four miles S. of Brightelmstone.

ROTTENEG, a town of Aultria; 13 miles S.W. of Freyhatt.

ROTTENMANN, a town of the duchy of Stiria; 20 miles

miles N.W. of Judenburg. N. lat.  $47^{\circ} 26'$ . E. long.  $14^{\circ} 8'$ .

ROTTENNESS, PUTREDO. See PUTREFACTION.

ROTTENSTEIN, in *Geography*, a town of Bohemia, in the circle of Koniggratz; eight miles W.N.W. of Geyersberg.

ROTTERDAM. See ANAMOOKA.

ROTTERDAM, a fortress in the island of Celebes, near Macassar, belonging to the Dutch. It lies about 800 feet from the beach, opposite to the road of Macassar, where a pier-head extends, which serves for unloading of the ships, and close to which there are 15 or 16 feet of water. The church is a neat building, and has room for 200 persons. The walls of the fortrefs are high and strong, and constructed of rock-stone. See VLAARDINGEN.—Also, a small island in the gulf of Manaar, near the W. coast of the island of Ceylon; 10 miles N. of Manaar.—Also, a town of America, in New York, on the N. side of Oneida lake.—Also, a city and sea-port of Holland, situated on a river named "Rotter," where it joins the Meuse. This place had the privileges of a city not long after the year 1270. It has been accustomed to hold the first rank in the assembly of the states among the small cities of Holland; and next to Amsterdam it used to be reckoned the richest and most flourishing city of the whole state, on account of the convenience of its harbour, where depth of water allowed the largest vessels to enter, and canals facilitated their loading and unloading at the warehouses of the merchants. The port of Rotterdam was more frequented by British traders than that of Amsterdam, because when vessels had weighed anchor, one tide brought them out to sea. Among the principal buildings are the town-house, the bank, the East and West India houses, the arsenal, and some of the churches, particularly that dedicated to St. Laurens. On the E. side of the city are a large basin and dock, for the purpose of building and launching vessels in the service of the Admiralty, and the East India Company. The magistracy consists of a council of 24, out of which are elected four burgomasters, a grand bailiff, and seven echevins. Besides the magistracy of the city, here are also three other tribunals, viz. the college of the grand bailiff, or dyckgrave of Schieland, and council, composed partly of nobility and partly of the cities of Rotterdam, Goude, and Schiedam, that hold their assemblies at Rotterdam, in a house called Landhuys, whose business it is to inspect the dykes, superintend the roads and canals, and take care of every thing that pertains to the environs of the city; the second tribunal is that of the judges of Schieland, whose jurisdiction extends over what does not belong particularly to the magistrates of cities; the third is the college of the lords of the admiralty for the Meuse, who have a house appropriated to that business. Rotterdam was the birth-place of Erasmus, and it is said that his statue still remains, and also the house in which he was born. The streets are long and generally narrow, and the foot pavement is only distinguished by a clean line of bricks; the population is estimated at about 48,000 people; 30 miles S.S.W. of Amsterdam. N. lat.  $51^{\circ} 55'$ . E. long.  $4^{\circ} 24'$ .

ROTTEES, a town of Norway; 50 miles N.E. of Romsdal.

ROTTI, an island in the gulf of Venice, near the coast of Friuli. N. lat.  $45^{\circ} 45'$ . E. long.  $12^{\circ} 9'$ .

ROTTINGEN, a town of the duchy of Wurzburg, on the Tauber; 13 miles W.N.W. of Rottenburg.

ROTTL, a river of Austria, which runs into the Danube, six miles above Lintz.

ROTTLERA, in *Botany*, is so called in honour of the

Rev. Dr. Rottler, Danish missionary at Tranquebar, who like several of his brethren in that remote situation, has alleviated his more serious occupations with the study of plants; and, besides acquiring himself a considerable knowledge of botany, has been eminently serviceable to the science, by his communications to his European friends. The original *Rottlera* of Willdenow proving the identical *Trewia nudiflora* of Linnæus, the present, chosen by Dr. Roxburgh, has been received subsequently by Willdenow, as well as in Hort. Kew. Thus the *Rottlera* of Vahl, in his *Enumeratio*, v. 1. 87, is superseded, and if a good genus, must have another name.—Roxb. Coromand. v. 2. 36. Willd. Sp. Pl. v. 4. 832. Ait. Hort. Kew. v. 5. 406.—Class and order, *Dioecia Icсандria*. Nat. Ord. *Tricocce*, Linn. *Euphorbia*, Juss.

Gen. Ch. Male, *Cal.* Perianth of one leaf; tube short; limb in four deep, ovate, reflexed segments; the two opposite ones rather the smallest. *Cor.* none. *Stam.* Filaments between thirty and forty, capillary, erect, inserted into the tube of the calyx, and about the length of its limb; anthers linear, cloven at each end.

Female, on a separate tree, *Cal.* Perianth inferior, bell-shaped, with four erect teeth. *Cor.* none. *Pist.* Germen superior, ovate, powdery; styles three, reflexed; stigmas feathery. *Peric.* Capsule roundish, powdery, three-lobed, three-celled, three-valved, the partitions from the centre of each valve. *Seeds* solitary, globose.

Ess. Ch. Male. Calyx deeply four-cleft, reflexed. Corolla none. Stamens thirty to forty.

Female. Calyx four-toothed, erect. Corolla none. Styles three. Capsule superior, three-lobed, three-celled. Seeds solitary.

1. *R. tinctoria*. Dyer's Rottlera. Roxb. Corom. v. 2. 36. t. 168.—Native of the inland mountainous parts of the circars of Hindoostan, flowering in the cold season. Dr. Roxburgh never found it any where else. This is a middle-sized, erect, branching tree. Leaves alternate, stalked, elliptic-oblong, acute, entire, from four to eight inches in length, three-ribbed and veiny; nearly smooth above; downy beneath; furnished at their base with two brown glands. Footstalks round, downy, from one to three inches long. Flowers small, in clusters, about the tops of the branches, axillary and terminal; the latter branched. Capsules the size of a small cherry, clothed with abundance of deep red granular powder, easily rubbed off. This powder is a valuable article of commerce, being much esteemed, especially among the Moors, for dyeing silk of a deep, bright, very beautiful and durable, full-orange or flame-colour. When the capsules are ripe, in February or March, they are gathered, and the powder carefully brushed off. It is preserved without any further process, and is sold to the merchants trading to Hydrabad, and other inland parts. This substance is but little acted upon by water, except with the admixture of alkaline salts, when it gives out a very deep blood-red colour. To spirits it communicates a rich, deep, reddish flame-colour; but in neither instance does it dissolve, the grains remaining entire, like sand. The inhabitants know this powder by the name of *Wassunta-gunda*, and use it in the following manner. To four parts of *Wassunta-gunda* are added one of alum, and two of salt of soda, native barilla. These are rubbed well together, with a portion of expressed oil of *Sesamum*, so small as hardly to be perceived. When well mixed, the whole is put into boiling water, in quantity proportioned to the silk which is to be dyed, and kept boiling smartly, more or less time, according to the shade required. The silk is turned frequently, to render the colour uniform.

ROTTOCOMB, in *Geography*, a town of Africa, in Bornou; 8 miles S. of Bornou.

ROTTOFREDO, a town of the duchy of Piacenza; 5 miles W. of Piacenza.

ROTTOLO, in *Commerce*, a weight used in Italy and the Levant. At Aleppo, and its port Scanderoon, the cantaro contains 100 rottoli, each of which is subdivided into 12 ounces, or 720 drachms; the great cantaro of Tripoli contains 175 rottoli, and the zurlo consists of 27½ rottoli. This rottolo, with which most sorts of goods are weighed, weighs 5lbs. avoirdupois nearly. The rottolo with which the silks from Tripoli, and other parts of Syria, are weighed, consists of 700 drachms, answering to 4⅞ avoirdupois. The rottolo used in weighing the Persian silks contains 680 drachms, or nearly 4¼ lbs. avoirdupois. The rottolo of Damascus, with which brasa, camphor, benzoin, spikenard, balsam of Mecca, and other drugs are weighed, contains 600 drachms, or 4½ lbs. avoirdupois. Five rottoli, or 3600 drachms, make what is called a *vesno*; which see. At Saide, in Syria, (the ancient Sidon,) silk and fatten yarn are weighed with the rottolo of Damascus, of 600 drachms; 100 such rottoli answering to about 410 lbs. avoirdupois. Heavy goods are weighed with the rottolo of Acre, 100 of which are = 482 lbs. avoirdupois. At Constantinople, the cantaro, or quintal, contains 44 okes, or 100 rottoli; and the cantaro weighs about 123⅞ lbs. avoirdupois, the oke 2 lbs. 13 oz., and the rottolo 19¼ oz., and the chequee 11¼ oz. avoirdupois. At Leghorn, the rottolo is 3 lbs. At Naples, the cantaro grosso contains 100 rottoli, each weighing 33½ ounces of the gold and silver weight, or 31⅞ ounces avoirdupois. Hence 28 rottoli = 55lbs. avoirdupois, and the cantaro grosso = 196⅞ lbs. avoirdupois. The cantaro piccolo is = 106 lbs. avoirdupois nearly.

In Sicily these different weights are used, *viz.* the rottolo grosso of 33 ounces, the rottolo foile of 30 ounces, and the libra, or pound of 12 ounces. 10 lbs. of Sicily = 7 lbs. avoirdupois nearly; and, therefore, 40 rottoli grossi, or 44 rottoli foile = 77lbs. avoirdupois. A cantaro grosso contains 100 rottoli grossi, or 192½ lbs. avoirdupois; a cantaro foile is 100 rottoli foilli, and is = 175 lbs. avoirdupois. At Smyrna, the cantaro, or kintal, contains 45 okes, or 100 rottoli. The batman is 6 okes, or 2400 drachms; and the oke is 400 drachms, and the rottolo = 180 drachms. The cantaro of 45 okes weighs 123 lbs. 4 oz. avoirdupois; and, therefore, the oke is = 2 lbs. 11 oz. 13 drs. avoirdupois. At Tripoli, the cantaro weight contains 100 rottoli, each of 6 ounces, or 128 termini; this cantaro answers to 168 lbs. peso foile of Venice, or about 12 lbs. avoirdupois. At Tunis, the cantaro contains 100 rottoli, each of 16 Tunis ounces, and weighs about 111 lbs. avoirdupois. Kelly's Cambit. See WEIGHT.

ROTULA, in *Anatomy*, the patella or knee-pan. See EXTREMITIES.

ROTULA, *Dislocations and Fractures of*, in *Surgery*. See FRACTURE, and LUXATION.

ROTULA, in *Natural History*, the name of a genus of the echini marini, of the general class of the placentæ. The characters of the rotulæ are, that they are flat shells in form of a cake, composed of various flat pieces, and formed into a round, something like that of a wheel, but wanting one or more parts of its outer ring, and radiated or dentated; their mouth is situated in the middle of the base, and the aperture of the anus in the third region of the axis, and marked with a cinquefoil flower at the summit. The great obvious character is, however, the dentated edge. Of this genus there are two known species.

ROTULA, in *Ichthyology*, is also a name given by some to the faber, or doree.

ROTULI *Magni Ingrassator*. See INGROSSATOR.

ROTULORUM CUSTOS. See CUSTOS.

ROTULUS, a roll. See ROLL.

ROTULUS *Contrarietium*. The earl of Lancaster taking part with the barons against king Edward II., it was not thought fit, in respect of their power, to call them rebels or traitors, but only *contrarietis*; accordingly, we have a record of those times called *rotulus contrarietium*.

ROTULUS *Wintonia*, an exact survey of all England, by counties, hundreds, and tithings, made under king Alfred, not unlike that of Domesday.

It was thus called, because anciently kept at Winchester among other records of the kingdom.

ROTUNDA FENESTRA, in *Anatomy*, an opening of the cochlea into the tympanum. See EAR.

ROTUNDA *Ligamenta Uteri*, two fibrous cords ascending from the uterus, and passing through the abdominal rings. See GENERATION.

ROTUNDO. See ROTONDO.

ROTUNDUM FORAMEN, in *Anatomy*, an opening of the sphenoid bone. See CRANIUM.

ROTUNDUS, a name given to several muscles from the roundness of their body.

Such are the *rotundus major*, called also *teres major*, and the *rotundus minor*, called also *teres minor*, and *transversalis*.

ROTUNDUS, *Pronator Radii*. See PRONATOR.

ROTZ, in *Geography*, a town of Aultria; 24 miles N. of Tulln.

ROTZHOF, a town of the duchy of Stiria, on the river Muehr; 16 miles S. of Gratz.

ROU, or PULO ROU, a small island in the Chinese sea, near the coast of Malacca. N. lat. 6° 43'. E. long. 102° 10'.

ROUAD. See RUAD.

ROUAGE, *Battery en*. See BATTERY.

ROUAÏTHA, in *Geography*. See ROAÏTHA.

ROUALTHA, a town of Arabia, in the province of Hedsjas; 108 miles S.S.E. of Mecca.

ROVANIEMI, a town of Sweden, in the government of Ulea, on the Keni; 55 miles N.N.E. of Tornea.

ROUARA, a town of South America, in Guiana.

ROVASIO, a town of France, in the department of the Sefia; 15 miles N. of Vercelli.

ROVATO, a town of Italy, in the department of the Mela; 10 miles W.N.W. of Brescia.

ROUBAIX, a town of France, in the department of the North, and chief place of a canton, in the district of Lille; 6 miles N.E. of Lille. The place contains 8091, and the canton 13,761 inhabitants, on a territory of 40 kilometres, in four communes.

ROUBAN, a town of Arabia, in the province of Hedsjas; 40 miles S. of Calaat el Moilah.

ROUBBIE', in *Commerce*, a gold coin of Turkey, which is one-third of the sequin, called Mahbub. See SEQUIN.

ROUCOU, or ROCOU, otherwise called *Annotto* and *Orlean*, is a red dye, formed in masses, from the pellicles of the seeds of an American tree. That which is commonly met with among us is moderately hard and dry, of a brown colour on the outside, and a dull red within. Labat informs us, that the Indians prepare a dye of this sort much superior to that which is brought to us; of a bright shining red colour, almost equal to carmine. For this purpose, instead of steeping and fermenting the seeds in water, they rub them with the hands, previously dipt in oil, till the pellicles come

off and are reduced into a clear paste, which is scraped off from the hands with a knife, and laid on a clean leaf, in the shade, to dry. De Laet, in his notes on Maregrave's Natural History of Brasil, mentions two kinds of roucou, or annotto; one of a permanent crimson colour, used as a *fucus*, and another which gives a colour inclining more to that of saffron. This last, which is our annotto, he supposes to be a mixture of the first sort with certain resinous matters, and with the juice of the root of the tree. See ANNOTTO.

ROUELLE, in *Geography*, a river of France, which rises near Le Quefnoy, and runs into the Scheldt, at Valenciennes.

ROUEN, a city of France, and capital of the department of the Lower Seine, situated on the Seine; before the revolution the capital of Normandy, and the see of an archbishop; 13 polls S.W. of Amiens. The place contains 87,000, and its six cantons 87,000 inhabitants, on a territory of 15 kilio-metres, in one commune. Rouen is large and commercial, has several manufactures, particularly of cotton, and contains 36 parish churches. In the market-place is a statue of the celebrated maid of Orleans, who was burnt here by the English for a witch. In 1117, when the French were defeated by the English in a battle fought here, the city belonged to the king of England, as a part of Normandy; but in the year 1204, it was surrendered to the king of France. In 1418, Henry V. of England commenced a siege which lasted five months; the inhabitants defending the city with persevering firmness and ardour, and enduring the most severe hardships; but they were at last obliged to surrender, on condition of paying 345,000 crowns of gold, and taking an oath of allegiance to the conqueror, who entered on the 19th of January 1419. N. lat. 49° 26'. E. long. 1° 10'.

ROUEN, in *Agriculture*, a term made use of to signify after-grass, or the hay made from this sort of grass. It is sometimes written *Rouwet*. See AFTER-Grass.

This sort of preserved grass is now found by many farmers, in different districts, to be of vast utility and advantage in the spring season for the support of some part of their store-sheep stock, as that of the ewes during the lambing-time, and those other sheep which are to be kept in good condition. In the county of Norfolk, Mr. Bevan has a high opinion of the great value and use of this kind of grass, sometimes preserving the quantity of twenty-eight or thirty acres of it in an excellent state for the ewes and lambs in the early spring. And near Swaffham, in the same county, Mr. Mason is in the practice of keeping grass of this nature from the end of July, and not turning at all into it until early in the spring of the following year, when the fattening bullocks and sheep, which have had hay during the winter, are put into it. The old grass is found to nurse up a great bite of young growth, and both together carry on the bullocks in a very favourable manner; it is also excellent for sheep; nothing at such a season is supposed to equal it. At Burnham, on an exposed piece of thirteen acres of this sort of grass, open to the sea, and the north-east wind, which Mr. Overman kept from Midsummer, ten score and sixteen ewes and their lambs were turned in on the 27th of March, and it kept them well a whole month. It is asserted, that they would have been half starved without it; but that by means of it they were fully supported, to the surprize of many who saw them feeding. This piece was fully *tated* in every part.

The same system of practice is also found equally useful and important in the county of Essex. Mr. Kitcher, of this district, is in the habit of laying up a pasture of this sort of spring food for his sheep, finding it of such astonishing use, that he is determined not to be without so great a resource.

And at Ongar, Mr. Dyer shuts up grass for the use of his sheep, both ewes and lambs, in March and the following month: it is found that the young grass shoots up with it in an extraordinary manner, and that his stock does better on it than on turnips. Also at Gosfield, Mr. Thurlow shuts up a space of grass from the beginning of September to the lambing-time, and finds it of very considerable advantage to his flock.

ROVER. See PIRATE.

ROVERBELLA, in *Geography*, a town of Italy; 12 miles N.N.W. of Mantua.

ROVEREDO, or ROVERETH, a town of the county of Tyrol, with a strong citadel, built by the lords of Castellbarco; but in the year 1414, it was taken from them by the Venetians, from whom Maximilian I. wrested it again by the sword, and incorporated it with the county of Tyrol. This town has a manufacture of fine silk, and carries on a great trade. The wine produced in this tract is called "Goccia d'oro," or golden drops. On Sept. 4th, 1796, Roveredo was taken by the French, after a battle in which the Austrians lost 7000 prisoners, 25 pieces of cannon, 50 waggons, and 7 standards; 8 miles S.E. of Trent. N. lat. 45° 53'. E. long. 11° 3'.

ROURGUE, a province of France before the revolution, about 25 leagues in length, and 18 in breadth, bounded on the E. and S. by Languedoc, on the W. by Quercy, and on the N. by Auvergne. The land, though not very fertile, produces much wood, and here are mines of copper, iron, sulphur, vitriol, &c. The principal rivers are the Tarn and the Lot. The capital city was Rhodéz. It now forms the department of the Aveyron.

ROVERO, a town of Italy, in the Trevisan; 9 miles E. of Cismone.

ROVERSANO, a town of Italy, in the department of the Rubicon; 20 miles W. of Rimini.

ROVERSCIO, AL, or *Per Roverscio*, Ital. in *Musie*, reversed, inverted. See RIVOLGIMENTO, and RIVOLTARE.

ROVES, in *Ship-Building*, small square pieces of iron with a hole punched in the middle, through which the nail goes, where it is clenched, and binds together the boards of pin-naces, yawls, &c.

ROVETTA, DON GIOVANNI BATISTA, in *Biography*, a Venetian composer, in great favour in the middle of the 17th century, vice maestro di cappello of St. Mark's cathedral, and composer of five or six operas. He likewise was author of *Masses and Madrigals a sei voci concertati*: in scoring one of them, we found the instrumental parts consisted only of two violins, and a base, wholly different from the voice-parts; but, except an introduction or symphony to each movement, and short ritornels, they had little to do. These madrigals were first published in 1625.

ROUEZ le Guillaume, in *Geography*, a town of France, in the department of the Sarthe; 3 miles S. of Sille.

ROUFFACH, a town of France, in the department of the Lower Rhine, and chief place of a canton, in the district of Colmar. The place contains 3292, and the canton 11,882 inhabitants, on a territory of 112½ kilometres, in eight communes.

ROUFFIGNAC, a town of France, in the department of the Dordogne; 9 miles S.W. of Montignac.

ROUGE, a town of France, in the department of the Lower Loire, and chief place of a canton, in the district of Chateaubriant. The place contains 2134, and the canton 7349 inhabitants, on a territory of 160 kilometres, in five communes.

ROUGE, *Cape*, or *Red Cape*, a cape on the N. side of the island of St. Domingo; four leagues W. of Point Isabellica.

Ufabellica.—Also, a cape called “Ras el Hamrah,” on the coast of Algiers. N. lat.  $37^{\circ} 5'$ . E. long.  $7^{\circ} 42'$ .

ROUGE River, a river of America, in Louisiana, so called from the colour of its waters, which are said to tinge those of the Mississippi in the time of the floods, rises in New Mexico, and after running about 600 miles, joins the Mississippi 187 miles above New Orleans,  $56\frac{1}{4}$  miles below Fort Rosalie, receiving 30 miles from its mouth the Noir, or black river. About 70 leagues up Rouge river the French had a considerable post, called Natchitoches, being a frontier to the Spanish settlements. Tobacco of a superior quality is cultivated at this post in considerable quantities, and sold at New Orleans.

ROUGE Chapeau, or Red Hat, a cape on the coast of North America. N. lat.  $46^{\circ} 31'$ . W. long.  $55^{\circ} 26'$ .

ROUGE-Croix, q. d. Red Cross. See POURSUIVANTS.

ROUGE-Dragon, q. d. Red Dragon. See POURSUIVANTS.

ROUGEMONT, in *Geography*, a town of France, in the department of the Doubs, and chief place of a canton, in the district of Baume; seven miles N. of Baume. The place contains 1260, and the canton 8290 inhabitants, on a territory of 170 kilometres, in 26 communes.

ROUGET, in *Ichthyology*, a name given by the French to the fish called the *lyra* and *capo* by authors. It is a species of the trigla, and is distinguished by Artedi by the name of the trigla with a long bifid snout and tubulous nostrils. See TRIGLA.

ROUGH, ROUGHNESS, in *Mechanics*. See FRICTION, and RESISTANCE.

ROUGH Casting. See PLASTERING.

ROUGH Diamond. See DIAMOND.

ROUGH Emerald. See EMERALD.

ROUGH-leaved Plants. See PLANT.

ROUGH Taste. See TASTE.

ROUGH-Tree Rails, in *Ship-Building*, are rails along the waist and quarters of ships, nearly breast high, to prevent persons from falling overboard. This term originated from the practice in merchant vessels of carrying their rough or spare gear in crutch irons along their waist.

ROUGH Rider, a person who is indispensably necessary in every cavalry regiment. He is a sort of non-commissioned officer, and should always associate with the sergeants in preference to the private men.

Rough riders are the assistants of the riding-master, and one should always be appointed to each troop. The necessary qualifications for every rough rider (independently of a thorough knowledge of horsemanship) are activity, zeal, and good conduct.

No rough rider ought to be an officer's servant, as his situation places him above the level of common men.

Rough riders are generally paid five guineas a-year as a compensation for their trouble; they likewise receive 10s. 6d. from every officer who learns to ride, and from every officer who has a horse broke at the riding school. This money is divided equally amongst them.

Every rough rider must provide himself with a proper jacket for the riding school business, according to the pattern fixed upon in the regiment.

When it is found absolutely necessary to employ non-commissioned officers as rough riders, they must do as much troop duty as they can.

ROUGH Horses, *To*, a word in familiar use among the dragoons to signify the act of breaking in horses, so as to adapt them to military purposes.

ROUGH it, *To*, a cant word used among military men, signifying to face every sort of hardship.

ROUGH Creek, in *Geography*, a river of Kentucky, which runs into Green river, N. lat.  $37^{\circ} 12'$ . E. long.  $87^{\circ} 35'$ .

ROUGH Skelly, a cape on the E. coast of Scotland. N. lat.  $56^{\circ} 36'$ . W. long.  $2^{\circ} 28'$ .

ROUGHCAST WASH, in *Rural Economy*, a sort of liquid wash, or application, employed for the purpose of being laid over the surfaces of outside walls, or buildings, of this nature, in order to preserve and ornament them. It is noticed by Mr. Vancouver, in his report of the state of the agriculture of the county of Devon, that a wash of this kind is getting greatly into use in that district. It consists, in this case, of four parts of pounded lime, three of sand, two of pounded wood-ashes, and one of the scoria of iron, intermixed very intimately together, and made sufficiently thin or fluid as to be applied by means of a brush. It is remarked, that when dry, it gives to the work the appearance of new Portland stone, and affords an excellent protection against the penetrating force of the south-westerly storms in that exposed county. It is also found useful for applying over the out-sides of stone buildings or walls.

ROUGHING CLOTH. See CLOTH.

ROUGHINGS, in *Agriculture*, a term sometimes applied to latter-grass, or aftermath, and sometimes to coarse pastures. They are always of the coarse rough tufty kinds, when this epithet is applied to them.

ROUGHY, in *Geography*, a river of Ireland, which falls with an impetuous current into the Kenmare river, about two miles E. of Kenmare town.

ROUGIES, a small island on the W. coast of France, being one of the group called the “Seven Islands.” N. lat.  $48^{\circ} 54'$ . W. long.  $3^{\circ} 21'$ .

ROUGNAT, a town of France, in the department of the Creuse; nine miles S. of Evaux.

ROUHA. See OURFA.

ROUHAMON, in *Botany*, a Caribbean name, retained by Aublet for one of his genera. See LASTIOSTOMA.

ROUIA, in *Geography*, a town of Syria, containing seven fine palaces, some of which are entire, and several churches built in a fine style; 36 miles S.S.W. of Aleppo.

ROUJAN, a town of France, in the department of the Herault, and chief place of a canton, in the district of Beziers; six miles N.W. of Pezenas. The place contains 1129, and the canton 5720 inhabitants, on a territory of 135 kilometres, in 11 communes.

ROVIGNO, or TREVIGNO, a sea-port town of Istria, seated on a rock which projects into the sea, with two harbours capable of containing the largest vessels. It contains about 17,000 inhabitants, chiefly fishermen and boat-builders. In its vicinity are quarries of beautiful marble; 68 miles E. of Venice. N. lat.  $45^{\circ} 10'$ . E. long.  $13^{\circ} 45'$ .

ROVIGO, a town of Italy, and capital of the Polcine di Rovigo, on the river Adigetto, the see of the bishop of Adria, to the decline of which town it owes its increase. It was anciently called Buonvico; it is surrounded with walls, turrets, and battlements. The river divides it into the upper and lower towns, and to the E. is a fortified castle. Exclusive of its suburbs, it is about a mile and a half in circumference, and contains six gates, a collegiate and nine other churches, together with several religious houses and hospitals; 37 miles S.S.W. of Venice. N. lat.  $45^{\circ} 4'$ . E. long.  $11^{\circ} 48'$ .—Also, a town of Italy, in the Vincentin, on the Adige; 14 miles S.S.W. of Vicenza.

ROUILLAC, a town of France, in the department of the Charente, and chief place of a canton, in the district of Angouleme; 12 miles N.W. of Angouleme. The

place contains 1168, and the canton 13,531 inhabitants, on a territory of 252½ kilometres, in 19 communes.

ROUILLE, PETER JULIAN, in *Biography*, a learned Jesuit, born at Tours in 1681, was educated in the Jesuits college of that city, and made his profession in the society in 1715. He successively taught the languages, philosophy, and mathematics in its seminaries. In 1724 he was called to Paris to assist father Catrou in the composition of his Roman History. To this work he only contributed the dissertations. He also revised and corrected the work of father d'Orleans, on the revolutions of Spain, and had a considerable share in the "Memoires de Trevoux" from December 1733 to February 1737. He had previously to this, in 1716, delivered "A Discourse on the Excellency and Utility of Mathematics," printed at Caen in 1716. He was author of some other works, and died, highly respected and esteemed, in the year 1740.

ROUILLY, in *Geography*, a town of France, in the department of the Vienne; 15 miles W. of Poitiers.

ROUL, ROLL, or *Rowl*, in the *Military Art*. Officers of the same rank, who mount the same guard, and take their turns in relieving one another, pursuant to some established roster, as captains with captains, subalterns with subalterns, and command according to the seniority of their commissions, are said to *roul* or *roll*.

ROULADE, Fr. in *Music*, a division or passage in a song of many notes to one syllable. (See DIVISION and NEUME.) A roulade is only an imitation of instrumental melody, either to grace a treble part, render an image more obvious, enforce the expression, or, when it is necessary, to suspend the discourse and prolong the melody. But it is likewise necessary that it should be on a long syllable, that the voice should be spirited, active, and capable of allowing the throat full liberty to warble and express with facility and neatness the notes of the division, without fatiguing the organs of the finger, and consequently the ears of the audience. Rousseau.

The vowels most proper for these flights are *a*, *o*, and *e*, open. The *i* and *u* are not sonorous, but distort the mouth: the diphthongs still more. (Rousseau is here considering the vocal properties of the French alphabet.) As to the nasal vowels or syllables, they should never be employed in roulades. The Italian language, in which the *a* and *o* abound, is more fit for inflexions of voice than the French; and these vowels are not spared by Italian composers, but brought into action as frequently as possible. On the contrary, the French, obliged to compose almost all their melodies to syllables instead of vowels, on account of their defects, are constrained to give the notes a slow and heavy motion, or to admit a class of consonants in accelerating syllables; which necessarily renders the melody languid or harsh. And we join with the citizen of Geneva in confessing, that we throw French vocal music can never surmount these inconveniencies.

"It is a vulgar prejudice to imagine, that divisions are improper in plaintive and pathetic airs; on the contrary, when the heart is moved and affected to an uncommon degree, the voice more easily finds accents of passion, than the mind can furnish words, and thence arise interjections in all languages. (See NEUME.) It is equally erroneous to imagine that a division is always proper, whenever a favourable vowel or syllable occurs, without considering the situation of the finger, and whether the sentiment, which he ought to express, authorizes it.

"Roulades are of modern invention. It does not appear that the ancients ever admitted them in their music, or ever gave them more than two notes to a syllable. And this

constitutes the difference between the two musics; one of which was subservient to the language, to which the other gives the law."

These reflections are admirable, deep, comprehensive, and convincing; yet, since they occurred to the penetrating author, more changes and refinements have happened in lyric poetry and singing, which make it necessary to extend this article, in order to keep pace with the times.

Till about the middle of the last century, many Italian composers gave divisions to *a*, *e*, and *o*, indiscriminately; all Farinelli's divisions are confined to the vowel *a*. (See a collection of them in Burney's Hist. Mus. vol. iv.) Even the vowel *o* closes the lips and teeth more than the Italian *a*, on which account, we suppose, it has been wholly refused divisions or roulades in its vocal music. See LANGUAGE, *Euphony of*, where this subject has been fully discussed.

ROULAND L'ÉGLISE, in *Geography*, a town of France, in the department of the Doubs; and chief place of a canton, in the district of Baume; nine miles N.E. of Besançon. The place contains 423, and the canton 9066 inhabitants, on a territory of 250 kilometres, in 33 communes.

ROULERS, a town of France, in the department of the Lys, and chief place of a canton, in the district of Courtnay. The place contains 8063, and the canton 13,587 inhabitants, on a territory of 37½ kilometres, in two communes.

ROULET, a town of France, in the department of the Charente; eight miles S.W. of Angouleme.

ROUM, *i. e.* the kingdom of the Romans, a name given to Natolia, by Solyman, sultan of the Turks, when he invaded and became master of it, in the 11th century. It is now chiefly applied to a part of Asiatic Turkey, extending from the Mediterranean to the Black sea, eastward of Caramania and Natolia, and westward of Armenia and the government of Diarbekir, including the governments of Sivas, Adana, and Marasch.

ROUM Kala, a small town and fort of Persia, in the pachalic of Orfa, situated on the western bank of the Euphrates, and inhabited by Turks and Arabs. It was formerly called Zeugma, from a Grecian term signifying a bride, and was the great passage for the Roman armies into Macedonia. There were two small towns, one on each side of the river; the former was called Zeugma, and the latter Apamea. A few miles farther down the river, the caravans travelling from Aleppo to Orfa, pass the Euphrates on a bridge of boats, at a place called "Bir," which, according to M. D'Anville, represents the ancient Bertha, 144 miles from Aleppo and 67 from Orfa, in N. lat. 36° 58'. (See BIR.) It is situated on an eminence on the bank of the Euphrates, protected by a citadel and a wall in a dilapidated condition. At this town, the houses of which are in a ruinous state, a tax is levied on all travellers and merchants who cross the Euphrates, which is here deep, rapid, and about 130 yards broad.

ROUMIEU, a town of France, in the department of the Gers; six miles E. of Condom.

ROUND, ROTUNDUS, in *Geometry*. See CIRCLE, GLOBE, and SPHERE.

ROUND, in *Anatomy*. See ROTUNDUS.

ROUND, in *Music*. A round in catch-books is sometimes called a *canon in the unison*, and sometimes, but erroneously, a *catch*: but it is distinct from both, being no more than a song of as many strains or sections, as parts; which, instead of being begun together, are performed after each other,

other, always singing different words and different notes in harmony with the rest; till a signal is given, by holding up the hand, for finishing upon the perfect chord of the key note, where the author has placed this final mark, ♮

ROUND is also used in music to denote a species of fugue. See *ROUNDELAY*.

ROUND, in *Military Language*, signifies a walk or turn, which an officer, commissioned or non-commissioned, attended with some soldiers, commonly six, takes in a garrison, or fortified place, *around* the ramparts in the night-time, to listen if any thing be stirring without the works, and to see that the sentinels are watchful, and do their duty, and all things are in good order.

In strict garrison the rounds go every half hour, that the rampart may be always furnished. The sentinels are to challenge at a distance, and to port their arms as the rounds pass, and let no one come near them. All guards turn out, challenge, exchange the parole, and present their arms, &c.

Rounds are ordinary and extraordinary. The ordinary rounds are three; the *town-major's round*, the *grand round*, and the *visiting round*.

ROUNDS, *Manner of going the*. When the town-major goes his round, he comes to the main guard, and demands a serjeant and four or six men to escort him to the next guard; and when it is dark one of the men is to carry a light.

As soon as the sentry at the guard perceives the round coming, he shall give notice to the guard, that they may be ready to turn out when ordered; and when the round is advanced within about twenty or thirty paces of the guard, he is to challenge briskly; and when he is answered by the serjeant who attends the round, *town-major's round*, he is to say, *stand, round!* and port his arms; after which he is to call out immediately, *serjeant, turn out the guard! town-major's round*. Upon the sentry calling the serjeant to turn out the guard, he immediately draws up the men in good order with shouldered arms, and the officer places himself at the head of it, with his sword drawn. He then orders the serjeant and four or six men to advance towards the round, and challenge; the serjeant of the round is to answer, *town-major's round*; upon which the serjeant of the guard replies, *advance, serjeant, with the parole!* at the same time ordering his men to rest their arms. The serjeant of the round advances alone, and gives the serjeant of the guard the parole in his ear, that none else may hear it; during which period, the serjeant of the guard holds the spear of his halbert or pike at the other's breast. The serjeant of the round then returns to his post, whilst the serjeant of the guard, leaving his men to keep the round from advancing, gives the parole to his officer. This being found right, the officer orders his serjeant to return to his men; says, *advance town-major's round!* and orders the guard to port their arms; upon which the serjeant of the guard orders his men to wheel back from the centre, and form a lane through which the town-major is to pass (the escort remaining where it was) and go up to the officer and give him the parole, laying his mouth to his ear. The officer holds the point of his sword at the town-major's breast whilst he gives the parole.

ROUNDS, *Grand*, the rounds which are gone by general officers, governors, commandants, or field-officers. When there are no officers of the day on picquet, the officer of the main guard in garrison may go the grand rounds.

ROUNDS, *Visiting*, rounds gone by captains, subalterns, and the town-majors of garrisons.

The grand rounds generally go at midnight; the visiting

rounds at intermediate periods, between sun-set and the reveillé. The grand rounds receive the parole, and all other rounds give it to the guards.

There is also a species of bastard rounds, if we may be permitted the expression, which are gone by a corporal and a file of men; and which are in reality nothing more than a patrol. When challenged, they answer *pat. rounds*.

N. B. The governor of a garrison can order the rounds to go as often as he may judge expedient. Extraordinary rounds are resorted to when any particular event or occurrence is expected, and in cases of tumult, &c.

ROUND *Robbin*, a compact of honour which officers enter into, (when they have cause of complaint against their superior officer) to state their grievances, and to endeavour to obtain redress, without subjecting one more than another to the odium of being a leader or chief mover. The term is a corruption of *ruban rond*, which signifies a round ribbon. It was usual among French officers when they signed a remonstrance, to write their names in a circular form, so that it was impossible to ascertain who signed first. Hence to sign a *round robbin* against any person, is for any specific number of men to sign, one and all, a remonstrance against him. Colonels of regiments have been sometimes treated in this manner. Great judgment, directing motives grounded upon strong facts, should always influence on these nice occasions.

ROUNDS, *Way of the*. See *WAY*.

ROUNDS, *Counter*. See *COUNTER-Round*.

ROUND, *Quarter*. See *QUARTER-Round*.

ROUNDS, among *Masons*, denote the broken pieces of statues.

ROUND-Heads. See *WHIG* and *TORY*.

ROUND-Head Nails. See *NAIL*.

ROUND-House, in *Ship-Building*, that part of the ship abaft, next above the quarter-deck, fitted up with cabins, &c. for the accommodation of the captain.

ROUND-Houses at the head, conveniencies, or seats of ease, for the officers.

ROUND-House also denotes a kind of prison, for the nightly watch to secure persons in, till they can be carried before a magistrate. See *WATCH*.

ROUND-In, or *Round-Aft*, at *Sea*, a term belonging to the main and fore-sail. When the wind largeth, they say, *Let rise the main-tacks, or the fore-tacks! Hale aft the fore-sheet to the cat-head; and the main-sheet to the cub-bridge-head!* And when these sheets are thus haled down, they keep them from flying up with the passerado rope. This work is called *rounding-in*, or *rounding-aft the sail*.

ROUND *Aft*, in *Ship-Building*, the segment of a circle which the stern partakes of from the wing-transom upward.

ROUND *Stern*, the stern of a vessel whose bottom, wales, &c. are wrought quite aft, and unite in the stern-post. Few English vessels are built on this construction, excepting small vessels, as hoys, &c.

ROUND-up of the *Transoms*, the segment of a circle to which they are sided, also of the beams and rails of the stern, to which they are moulded.

ROUND *Niche, Roof, Seam, Sbot, Splice, Table, Top*. See the substantives.

ROUND, in the *Academies*, denotes a circular piste or tread.

ROUND a *Horse, To*, is a general term for all sorts of maneges, upon a volt, or circular tread.

Hence, to round a horse upon a trot, gallop, &c. is to make him carry his shoulders and haunches roundly or compactly, upon a larger or smaller circle, without traversing or bearing to a side.

**ROUND Table**, the circular table at which the knights of old, who assembled together from different countries to perform the martial exercises of the tournament, were accustomed to eat, on such occasions, to prevent disputes about precedence. Such a table is seen fixed to the eastern wall of the county-hall at Winchester, being vulgarly called "Arthur's Round Table," though it does not appear to be more ancient than the reign of king Stephen. From the use to which these tables were appropriated, the diversion itself of the tournament, or tilting, was called the round table. "Illustris miles, Rogerus de Mortuo-mari apud Kenilworth ludum militare quem vocant rotundam tabulam centum militum ac tot dominarum constituit." Th. Walsingham, *Hist.* p. 49.

**ROUND Towers**, those tall slender towers which are almost peculiar to Ireland (some few being found in Scotland), rising to the height of from 50 to 100 feet, or more, and containing not more than five or six feet in diameter in their upper chamber. They have a single entrance-door, of from five to fifteen feet from the ground, and a loop-hole, to give light to each story, of which there are generally six or seven in each round tower. The uppermost story, however, which was the usual dwelling-place of the solitary inhabitant, was furnished with four loop-holes or windows, corresponding with the four cardinal points of the compass. From the nature and situation of these singular structures, they being always very near to the site of an ancient church, it appears that each of them was built for the habitation of a single *Inclusus*, or hermit, who, living in the highest chamber of it, enjoyed his beloved solitude as much as if he had dwelt in a desert. It appears from Giraldus Cambrensis, that Ireland was full of these towers in the 12th century, and there is reason to ascribe the erection of them to the sixth, seventh, and eighth centuries, namely, before the Danish invasions, and during the period of the Irish transmigration into various countries in quest of solitudes. The idea of them and their use were evidently borrowed from the columns and stylices of the East. See **STYLITES**.

**ROUND Bay**, in *Geography*, a bay with good anchorage, on the W. coast of St. Lucia.

**ROUND Cape**, a cape on the coast of Patagonia, in the straits of Magellan. S. lat.  $53^{\circ} 47'$ . W. long.  $71^{\circ} 32'$ .

**ROUND Hill**, an island in the North Pacific ocean, near the E. coast of Labrador. N. lat.  $53^{\circ} 25'$ . W. long.  $55^{\circ} 16'$ .

**ROUND Hill Bluff**, a cape on the N. coast of Jamaica, W. of Montego bay. N. lat.  $18^{\circ} 29'$ . W. long.  $77^{\circ} 58'$ .

**ROUND Heads**, Indians of North America, inhabiting the territory on Round river. The number of warriors is about 2000.

**ROUND Island**, a small island of England, in Pool harbour.—Also, a small island near the E. coast of Borneo, in the bay of Gunong Tellu. S. lat.  $0^{\circ} 23'$ . E. long.  $123^{\circ} 30'$ .

**ROUND Key**, a small island near the coast of West Florida, which is well timbered. N. lat.  $30^{\circ} 15'$ . W. long.  $88^{\circ} 28'$ .

**ROUND Rock**, one of the Virgin islands, in the West Indies. N. lat.  $18^{\circ} 10'$ . W. long.  $62^{\circ} 53'$ .

**ROUNDELAY**, or **ROUND**, a kind of ancient poem, thus called, according to Menage, from its form; and because it still turns back again to the first verse, and thus goes round.

The word is formed from *round* and *lay*. The French call it *rondeau*; the Spaniards *glofes*.

The common roundelay consists of thirteen verses, eight

of which are of one rhyme, and five in another. It is divided into couplets; at the end of the second and third of which, the beginning of the roundelay is repeated; and that, if possible, in an equivocal or punning sense.

The roundelay is a popular poem among the French, but little known among us. Marot and Voiture have succeeded the best in it.

Rapin observes, that if the roundelay be not very exquisite, it is intolerably bad. In all the ancient roundelays, Menage observes, that the verse preceding has a complete sense, and yet joins agreeably with that of the clofe; without depending necessarily on it. This rule, well observed, makes the roundelay more ingenious, and is one of the finesses of the poem.

Some of the ancient writers speak of the roundelay, or roundel, as a kind of air appropriated to dancing; and in this sense the term seems to indicate little more than dancing in a circle, with the hands joined. See **RONDEAU**.

**ROUNDELET**. See **RUNDELET**.

**ROUNDING**, in *Sea Language*, denotes certain old ropes wound firmly and closely about that part of a cable which lies in the hawse, or under the ship's bow, or athwart the stem. It is used to prevent the surface of the cable from being chafed or fretted in those places.

**ROUNDING-in** generally implies the act of pulling upon any rope which passes through one or more blocks, in a direction merely horizontal; as round-in the weather-braces, &c. It seems to be derived from the circular motion of the rope about the sheave or pulley through which it passes.

**ROUNDING-up** is expressed of a tackle which hangs in a perpendicular position, without sustaining or hoisting any weighty body; in which case it is the operation of pulling the blocks closer to each other, by means of the rope which passes through them, to compose the tackle; and is opposed to over-hauling, by which the blocks are drawn farther asunder.

**ROUNDNESS**, **ROTUNDITY**, in *Physics*. See **SPHERICITY**.

**ROUND**, or **ROUNDELAY**, in *Music*, a kind of burden or ritornello; where the beginning of each couplet is repeated at the end of it.

**ROUNDSTONE BAY**, in *Geography*, a harbour of the county of Galway, Ireland, in Ballinahinch. It is separated from Birterhui bay by the island of Inishkeele, lying on the west of it.

**ROUNREAK**, a town of Pegu, on an island formed by the Ava; 42 miles S. of Lundfay.

**ROUP**, in *Commerce*, a silver coin of Turkey, containing 10 paras, the para being equal to 3 aspers, and 40 paras being equal to the dollar or piastre.

**ROUP**, in *Poultry*, is a filthy boil or swelling upon their rumps, known by the staring, or turning back of the feathers.

The roup, if not soon remedied, will corrupt the whole body; to prevent which, the feathers are to be pulled away, the swelling laid open, and the matter pressed out; after which the part is to be washed with salt and water, or brine.

**ROUPALA**, in *Botany*, a name of Aublet. See **RHOPALA**.

**ROUPEYROUX**, in *Geography*, a town of France, in the department of the Aveyron; 7 miles S.E. of Villafanche.

**ROUPIA**, or **RUPER**. See **RUPEE**.

**ROURFA**, in *Botany*, a name of Aublet's. See **ROBERGIA**.

**ROUSAY**, in *Geography*, one of the Orkney islands, Scotland, is situated to the north-west of the Mainland of Orkney, from which it is separated by a strait about a mile in breadth. It consists chiefly of a ridge of lofty hills declining on all sides towards the coast. The best cultivated parts of this island are its eastern and south-western sides; but there is a narrow strip of arable land extending round the whole shore. The hills are mostly covered with heath, intermixed with various kinds of grasses, which afford sustenance to a great number of sheep, swine, and black cattle. Opposite to the Mainland, in a romantic situation, stands the house of Westness, which in remote ages was the abode of the celebrated earl Sigard, who fell in the famous battle of Clontarf in Ireland, and is ranked by historians among the greatest heroes of his age. On a flat tract of land, close to the shore, about a quarter of a mile westward from the place, are several "immense piles of stones, evidently the ruins of some ancient structure, around which are to be seen graves formed with stones set on edge, as in some other places; and the name of Swendrow, which it bears, points it out, with great probability, as the scene of the capture of earl Paul, by Swein, the son of Asleif, and the slaughter of his attendants, when he was, with the basest intention, carried a prisoner into Scotland." The ridge known by the whimsical name of the camp of Jupiter Fring, is situated about two miles eastward from Westness. Several standing stones are to be met with in different parts of the island; and there are some tumuli on the south side, near the Froit, also a few Picts-houses.

Contiguous to Rousay, on the north-west, is the small island of Eaglehay, which yields to none of the Orkney isles in beauty of appearance, or convenience of situation. This island is about two miles long and one broad, and, in conjunction with Rousay, forms one parish; which, according to the population census of 1811, contained 189 houses, and 965 inhabitants. Eaglehay is remarkable in history for having been the scene of the unjust and barbarous murder of St. Magnus, the tutelary saint of the Orkney islands. The church, which is very ancient, is said to occupy the spot on which the assassination was committed. Owing to the natural attractions of this island, several of the counts of Orkney made it their usual place of residence, and their example was followed in later times, when it became the property of the Douglasses and the Monteaths. History of the Orkney Islands, by the Rev. Dr. Barry, 2d edit. by the Rev. James Headrick, 4to. London, 1808.

**ROUSE up a Hare**, among *Hunters*. See **HUNTING**.

**ROUSE, To**, among *Falconers*, is when a hawk lifts up and shakes himself.

**ROUSHOLM HEAD**, in *Geography*, a cape on the S.W. coast of the island of Stronfa. N. lat. 58° 56'. W. long. 2° 34'.

**ROUSSE, Grand and Petit**, rocks in the English Channel; 5 miles N.E. from the island of Jersey.

**ROUSSEA**, in *Botany*, was so called by the writer of the present article, in memory of the celebrated Jean Jacques Rousseau. Botany had spread a charm over the latter years of this distinguished man, and soothed their real or imaginary ills. Whenever he touches on this favourite subject, he communicates the same charm to his readers. Such has been the effect of his example, perhaps above all others, that he would now no longer have to deplore "the gross ignorance and barbarism" of the French, who, about fifty years ago, stared at a botanist with sovereign contempt. His letters on the science have rendered the Linnæan system popular all over Europe. He corresponded with Linnæus, who had dedicated a genus to his name;

which the younger Linnæus, through misapprehension, published as *Ruffelia*, and which is now called *Vahlia*, there being already a *Ruffelia*, named by Jacquin. What we are about to describe was therefore selected as a very fine and singular genus, and it has been generally adopted, both in France and elsewhere.—Smith Plant. Ic. fasc. 1. 6. Schreb. Gen. 792. Willd. Sp. Pl. v. 1. 607. Mart. Mill. Dict. v. 4. Juss. in Sims and Kon. Ann. of Bot. v. 2. 568. Lamarck Illustr. t. 75.—Class and order, *Tetrandria Monogynia*. Nat. Ord. *Campanaceæ*, Linn. Juss.

**Gen. Ch.** Cal. Perianth inferior, of one leaf, in four deep, equal, widely spreading, tongue-shaped, permanent segments. **Cor.** of one petal, externally rugose; tube nearly globular, almost as long as the calyx; limb in four equal, lanceolate, acute, revolute segments. **Stam.** Filaments four, erect, equal, linear, flattened, somewhat tapering upwards, longer than the corolla; anthers terminal, small, arrow-shaped. **Pist.** Germen superior, pyramidal, quadrangular; style terminal, square, permanent, the length of the stamens; stigma funnel-shaped. **Peric.** Berry? pyramidal, quadrangular, of one cell? with a coriaceous coat. **Seeds** very numerous, lenticular, imbedded in pulp.

**Eil. Ch.** Calyx in four deep segments. Corolla bell-shaped, four-cleft, inferior. Berry? quadrangular, with many seeds.

1. *R. simplex*. Sm. Ic. t. 6. Willd. n. 1.—Gathered by Commerçon in the island of Mauritius, and communicated by Thouin to the younger Linnæus, with about 1500 fine plants besides. This appears to be a *scrub*, of a fleshy habit, climbing over mossy rocks, or stems of trees, in moist situations. The *stem* is thick and knotty. *Leaves* opposite, in pairs crossing each other, stalked, simple, obovate, rather fleshy, daintly toothed, pointed, quite smooth on both sides, with a solitary rib, and many fine transverse veins; their length about three inches; breadth one, or one and a half. *Footstalks* an inch long, even, channelled, smooth. *Stipulas* opposite, between the footstalks, triangular, acute, membranous. *Flowers* solitary, axillary, large, fleshy, on drooping round stalks, rather shorter than those of the leaves, accompanied at the base of the stalk by several crowded, membranous, acute *bracteas*, very like the *stipulas*. *Calyx* smooth, an inch long. *Corolla* somewhat downy at the outside; of its colour we have no means of judging. The *fruit* appears to be a coriaceous berry, about an inch in diameter, but we have not seen it fully formed, nor has Commerçon left any note respecting the qualities of the plant. In the texture, and external downiness, of the *corolla*, this genus accords not so much with *Campanula* itself, as with others of the same order, *Goodenia*, *Scævola*, &c. To some of these the form of its *stigma* approaches, while the *anthers*, so widely differing among themselves in this order, are, in the present instance, very unlike most of the other genera. The opposite *leaves*, and intermediate *stipulas*, evince, as M. de Jussieu observes, an approach in habit to the natural order of **RUBIACEÆ**. See that article.

**ROUSSEAU, JOHN BAPTIST**, in *Biography*, a French poet of considerable celebrity, was born at Paris in 1671. His father, though only a shoe-maker, contrived to give him a liberal education. By his literary talents he obtained, while very young, admission among persons of rank and taste. In 1688 he attended the French ambassador to the court of Denmark, in quality of page. After this he went with marshall Tallard to England, where he contracted an intimacy with Saint Evremont. In 1703 he was domiciliated with M. Rouillé, director of the finances, whom he accompanied to court, and elsewhere, living in tranquillity

in the midst of splendour, and cultivating the Muses, to the neglect of those opportunities which occurred to him of making his fortune. When he was at the height of his reputation, he involved himself in an affair which put an end to his happiness, and rendered him wretched for the remainder of his life. A number of men of letters were accustomed to meet at a coffee-house in Paris, among whom were Rousseau and La Motte, when, in 1708, the opera of *Hesione* made its appearance. Rousseau wrote some verses upon the authors of the words, the music, and the ballet of the piece, which were highly satirical. These were anonymous, and were imputed to Rousseau, who not only denied them, but attempted to fix the blame upon M. Saurin, a man of science and letters, who, from a Calvinist minister, had become a convert to Popery, and resided in Paris. The nature of this discussion it is not necessary to go into, it is sufficient to say, that by an arrêt of parliament, in 1712 Rousseau was condemned to perpetual banishment from the kingdom, not only as a suborner in the accusation of Saurin, but as the author and distributor of the satirical verses. He had already retired to Switzerland, where he was protected by the count de Luc, the French ambassador to the Cantons. He published in Soleure the first edition of his collected works, in the preface to which he ridiculously gives himself the air of one who wrote verses for mere amusement, although it was by his poetry alone he obtained public notice and the favour of the great. When De Luc went to Baden, in 1714, as plenipotentiary for concluding peace with the emperor, Rousseau accompanied him. He there became known to prince Eugene, and by him was taken to Vienna. Here he resided three years, but not being able to restrain himself from exercising his satirical talent, he was obliged to quit that capital for Brussels, in haste. At Brussels he became acquainted with Voltaire, with whom he formed a confidential intimacy, which however did not last very long: jealous of each other's fame, they became bitter enemies, not only endeavouring to blacken each other's moral character, but each, at the expence of his own judgment, depreciating the literary merit of his adversary. Rousseau longed much to revisit Paris, and made intercession with the regent duke of Orleans, who granted him letters of recall, but the poet insisted upon a previous revision of his trial, which he could not obtain. In 1721 he came to England, where he prepared a new edition of his works. This was published in 1723, in two vols. 4to. and produced him 10,000 crowns, which he placed in the fund of the Ostend company. The failure of this company sunk all his fortune, and he was reduced, in the decline of life, to subsist on the benevolence of his friends. Boutet, a notary of Paris, supplied his most urgent wants, but he met with more effectual assistance from the duke d'Artemberg, who, when he quitted Brussels in 1733, settled upon him a handsome pension, besides giving him an apartment and his table in his palace. Rousseau displeased this patron, by calumniating Voltaire, and determined to go to Paris, with the hope of finally obtaining a repeal of his banishment. He had prepared his way by two epistles to persons of weight in that city, and by an ode to the praise of cardinal Fleury on the peace. His efforts were, however, unsuccessful. He could not even obtain a safe-guard for passing a single year in Paris: he accordingly returned to Brussels, where he died in March 1741, at the age of 70. In his last moments he declared he was not the author of the couplets for which he had been banished. The estimate of his moral character depends so much on the belief of his guilt or innocence, in the points respecting which he was accused, that nothing can be more different than its statement by his friends and enemies. There is more agree-

ment in the opinions of his countrymen relative to his poetical character, and it is pretty generally acknowledged that he stands at the head of the ode writers in the French language. "To these compositions," adds his biographer, "he brought great fire and force of expression, copiousness, and grandeur of imagery, and all the harmony of which his language is capable; but the sentiment is generally common, and nothing indicates a soul of the superior order." Of his "Odes" there are four books, of which the first consists of sacred topics, taken from the Psalms. He wrote two books of "Epistles" in verse; "Cantatas;" "Allegories;" "Epigrams;" "Miscellaneous Poems;" "Four Comedies in Verse and three in Prose;" and a "Collection of Letters." These are said to give an unfavourable idea of his temper, but some allowance should be made for a man who was so long an object of the persecution of his enemies, and of whom it was said in his epitaph, that "thirty years he was an object of envy, and thirty of compassion." M. Seguy, in concert with M. the prince of la Tour Tassis, has given a beautiful edition of his works, agreeably to the poet's last corrections. This edition was printed at Paris in 1743, in three vols. 4to. and in four vols. 12mo. containing nothing but what the author acknowledged as his own. Ferron speaks of Rousseau as uniting in himself the excellencies of Pindar, Horace, Anacreon, and Malherbe. He was in habits of correspondence with the abbé d'Olivet, the two Racines, the celebrated Rollin, and other illustrious French characters.

ROUSSEAU, JEAN JACQUES, was born at Geneva in the year 1712. His father was a watch-maker. At his birth, which, he says, was the first of his misfortunes, he endangered the life of his mother, and he himself was for a long time in a very languishing state of health; but as his bodily strength increased, his mental powers gradually opened, and afforded the happiest presages of future greatness. His father, who was a citizen of Geneva, was a well-informed man, and in his shop, he always kept by him some literary works of authority, among which were Plutarch's Lives, with which he intermixed such conversations as might be expected from an ardent republican. In his "Confessions," to which all the biographers of Rousseau must go for information, he has recorded several circumstances, which, in his opinion, exerted a lasting influence upon his character; but it is more probable that his ruling propensities were determined by his bodily constitution. This he represents as of the warmest kind, burning with sensuality from his very birth. His school education was very imperfect, and he grew up in habits of idleness, and in the vices of a weak unsteady temper. He was first put apprentice to an attorney, who soon discharged him for his negligence: after this he was put out to an engraver, who disgusted him by his harshness. The fear of chastisement, which he probably well merited, rendered him a fugitive from his master, when he was in his 15th year, at which time he was a restless discontented being, consumed with desires of which he knew not the object, and exalting his fancies for want of realities. He went into Savoy, where he was hospitably entertained by a parish priest, who pleased himself with the idea of making a proselyte from the Genevan reformed church. For this purpose he sent the youth to Annecy, to a Madame de Warrens, an ingenious and very amiable lady, who had, in 1726, left part of her wealth, and the Protestant religion, in order to throw herself into the bosom of the church. This generous lady served in the triple capacity of a mother, a friend, and a lover to the new proselyte, whom she regarded as her son. For farther instruction she sent him to a seminary at Turin, where his conversion was completed, and

and he got twenty florins in exchange with his new religion. When this money was spent, he found no better resource than to enter into the service of a countess: here he committed a crime, which he acknowledges, in his "Confessions," with the most heartfelt remorse. He stole a ribbon, and when it was found in his possession, he not only denied the theft, but charged an innocent and amiable young woman in the house with it, to whom, in fact, he meant to have presented the ribbon. After the death of the countess, he entered into the family of a nobleman, whose son, a literary man, took pains to instruct him, and treated him rather as a companion or pupil than a servant. But the flattering prospects opened to him by this connection he destroyed by his imprudence and misconduct, and being turned out of doors, after passing some time as a vagabond, he returned to Madame de Warrens. This lady had found means to ally her devotional turn of mind with the indulgence of amorous propensities, of which young Rousseau was an object, though not the only one. Through her interest he obtained a place as secretary to a commission, appointed by the king of Sardinia for surveying lands, and in this employ he continued two years, during which he applied himself to the study of arithmetic and geometry. Music, however, became his passion, and growing disgusted with his other occupation, he renounced it, and took up the profession of music-master at Chamberry. Here he passed eight years, intimately connected with Madame de Warrens, though not without following her example of occasional deviations to other favourites. At length a coldness took place, and Rousseau was recommended by her to the office of tutor to the children of M. Mably, at Lyons. He did not retain this situation very long, but went to Paris, where he lived in obscurity till 1743, when he obtained the appointment of secretary to the French ambassador to the republic of Venice. It was not long before he quarrelled with his superior, and returning to Paris, with an improved knowledge and taste in music, he lived by it, at the same time employing his leisure in the study of natural philosophy and botany. He was for some time clerk to a farmer-general, and with part of the profits which he gained in this situation he repaid some of the pecuniary assistance he had received from Madame de Warrens, who now stood in need of it. In 1748 he began to feel the attacks of a painful disorder, which troubled him during the remainder of his life, and by incapacitating him for active employments, might perhaps be a remote cause of his literary fame. The year 1750 was the commencement of his literary career. The academy of Dijon had proposed the following question, "Whether the revival of the arts and sciences has contributed to the refinement of manners." Rousseau, it is said, at first inclined to the affirmative side of the question; but by the persuasion of Diderot he was induced to support the negative, as most likely to attract notice. His discourse against the advantages of the sciences accordingly having been found to be the best written, and replete with the deepest reasoning, was publicly crowned with the approbation of this learned body, and was generally read with the interest usually inspired by a splendid paradox. Several answers appeared against it, one of which was written by Stanislaus, king of Poland: it was enough for Rousseau to have made his name known with so much distinction in the literary world. The part which he took seems to have made a lasting impression upon him, in preference of the savage to the civilized life, which was so frequent a subject of his declamation. Among other attacks which this discourse drew upon him, was that of being ridiculed on the stage of Nancy, by Palissot, in his "Comedie des Philosophes." The king of Poland, then duke of Lorraine, was

so much displeased with this insult, that he caused a letter of apology to be written to Rousseau, at the same time acquainting him that he had deprived Palissot of his place at the academy of Nancy, and it is highly to the credit of the philosopher, that he immediately interceded for him and obtained his restoration.

In 1752 Rousseau wrote a comedy, entitled "Narcisse, ou l'Amant de lui-même." He also composed a musical entertainment of "Le Devin du Village," which was represented with the greatest success at Paris. His next piece was "Lettre sur la Musique Françoise," which was to prove that the French had no such thing as vocal music, and that, from the defects in their language, they could not have it. The letter was written with much taste, and shewed a deep knowledge of the subject of which he was treating, but it brought down upon his head a storm of resentment, even to the burning of him in effigy. In 1754 he returned to Geneva, where he abjured the Catholic faith, and was restored to the rights of citizenship. For this favour he made a return by the patriotic, and truly eloquent dedication to the republic, of his "Discours sur les Causes de l'Inégalité parmi les Hommes, et sur l'Origine des Sociétés." No one could give better advice to his fellow-citizens than Rousseau has done in his dedication. The work itself is full of almost unintelligible maxims and wild ideas; and was written with a view to prove that mankind are equal; that they were born to live apart from each other; and that they have perverted the order of nature in forming societies. He bestows the highest praise on the state of nature, and deprecates the idea of every social compact. It is, however, rhetorical rather than argumentative, and is over-run with much idle declamation in praise of a savage, and depreciation of a civilized state, which the author repeated so often till he probably believed the paradox. Our author did not remain long at Geneva, but returned to France, and lived some time at Paris, after which he retired to Montmorency, as a studious solitary, and published, in 1758, his "Lettre" to M. D'Alembert on the design of establishing a theatre at Geneva. This tract is written with great force of reasoning, and shews that the author had made the most profound observations on life and manners; and he seems to have carried his point in proving that a theatre could not be necessary in a place circumstanced as Geneva was. This work is thought to have laid the foundation of that hatred which Voltaire never ceased to entertain for the Genevan philosopher. Replies were written by D'Alembert and Marmontel.

In 1760 Rousseau published his celebrated novel, entitled "Lettres de deux Amans, &c." but generally known by the title of "Julie, ou la Nouvelle Héloïse." This epistolary romance, of which the plot is ill-managed, and the arrangement bad, like all other works of genius, has its beauties as well as its defects. Some of the letters are, indeed, admirable, from the force and the warmth of expression, from an effervescence of sentiments, from the irregularity of ideas which always characterize a passion carried to its height. By one critic it has been assumed that none of the personages of this novel are really interesting. "That of St. Preux is weak, and often forced. Julia is an assemblage of tenderness and pity, of elevation of soul, and of coquetry, of natural parts and pedantry. Wolmar is a violent man, and almost beyond the limits of nature. In fine, when he wishes to change his style, and adopt that of the speaker, he does not long support it, and every attempt embarrasses the author and cools the reader. In the Héloïse, Rousseau's talent of rendering every thing problematical, appears very conspicuous, as, in his arguments in favour of, and against, duelling, which afford an apology for suicide, and a just condemnation

denmation of it; of his facility in palliating the crime of adultery, and his strong reasons to make it abhorred; on the one hand, in declamations against social happiness, on the other in transports in favour of humanity; here in violent rhapsodies against philosophers; there by a rage for adopting their opinions; the existence of God is attacked by sophistry, and Atheists confuted by the most irrefragable arguments; the Christian religion combated by the most specious objections, and celebrated by the most sublime eulogies." In the preface to this work the author attempts to justify his consistency; he says public spectacles are necessary for great cities, and romances for a corrupted people. "I have," he adds, "viewed the manners of my age, and have published these letters. Why did I not live at a time when I ought to have thrown them into the fire." He affects also to say that they were not intended for an extensive circulation, and that they will suit but few readers. With regard to their effects on the female sex, he pretends to satisfy his conscience with saying "No chaste young woman ever reads romances; and I have given this book a decisive title, that on opening it a reader may know what to expect. She who, notwithstanding, shall dare to read a single page is undone; but let her not impute her ruin to me—the mischief was done before." This is mere rant, and the extreme of vanity. Rousseau rendered his work as seductive as possible, and would have been mortified beyond measure could he have believed that it could readily have been laid aside by any one who had opened it. Besides, had he been that moral man which he would affect to be, he ought, knowing its tendency, to have committed it to the flames, instead of sending it to the press. In truth, he assumes in it the tone of a moral teacher of the highest order, nor will it be denied that, amidst much improper matter, it contains many lessons of domestic prudence and exalted virtue. "In warmth of painting, and eloquence of sentiment, it must be allowed to have no superior in its class; in moral inconsistency and improbability, scarcely unequal. With a profound knowledge of the human heart, it joins great ignorance of life and manners; with much sober and useful truth, all the extravagance of exaggerated feeling. It is a dangerous work, but has been the parent of others still more dangerous, because affording easier objects of imitation."

Rousseau's next work was entitled "Du Contrat Social, ou Principes du Droit Politique," which was said to be a mere extract from one on a much larger scale, which he had commenced, but which he had long since abandoned as beyond his powers. In this he is the fearless and intrepid vindicator of republicanism, and is supposed to have done much to excite the late disastrous French revolution. The work was prohibited in France and Switzerland; and from its publication may be dated that warfare between the author, and the supporters of existing establishments, civil and religious, which exposed the remainder of his life to persecution.

In 1762 Rousseau published his "Emilie, ou de l'Education," which may be regarded as his principal work, as it was that in which he most boldly attacked or opposed the commonly received opinions, and, in consequence, excited against himself the greatest mass of hostility. The fundamental idea of Rousseau in education is to suffer the youthful mind to develop by itself, rather preventing it from imbibing any thing mischievous, than hastening to impress it with lessons of preceptive instruction; presenting to it objects of nature rather than of art, and regulating the conduct more by restraints of necessity than of principle, till a foundation is laid for the operation of reason unbiassed by habit and prejudice. Rousseau's pupil is to follow nature in every

thing; the precepts of the philosopher are expressed with the force and dignity of a mind full of the leading truths of morality. If he himself has not always been virtuous, nobody has felt its force more, or made it appear to more advantage; and he merits great applause for the manly and independent spirit, the contempt for luxurious indulgencies and idle parade, which he every where inculcates. The author excited against himself almost all the religious world, by the manner in which he spoke of the attempts to furnish the youthful mind with theological ideas. Yet no one could more eloquently extol the morals of the gospel and the character of its founder than he has done; by this praise, and his sentiments of piety, he displeased the French philosophers, so that there was scarcely any party of men to whom he did not stand in opposition. Of these, however, the most formidable of his antagonists were those possessed of authority. The French parliament condemned this book in 1762, and entered into a criminal prosecution against the author, which forced him to a precipitate retreat. He directed his steps to his native country, but Geneva shut her gates against him. Both at Paris and Geneva, the "Emilie" was burnt by the common hangman: ridiculous attempt of ridiculous governments to stop the circulation of opinions! The book still exists, and, notwithstanding the many and serious objections to which it is liable, deserves to exist, while its tyrannical persecutors have long since been forgotten, and their puny efforts laughed at by every man possessed of an understanding superior to that of an idiot. Rousseau was for a time allowed to take shelter in Switzerland, where he was most hospitably treated by marshal Keith. He there published a letter to the archbishop of Paris, in answer to his *Mandement* for the burning of the "Emilie:" and also his "Lettres de la Montagne," which contained a severe remonstrance against the proceedings of the republic of Geneva in his condemnation, the citizenship of which state he formally renounced. That he thought very highly of this work is evident from the following passage: "How," says he, "can I enter into a justification of this work? I who think that I have effaced by it the faults of my whole life; I, who place the evils it has drawn upon me as a balance to those which I have committed; I who, filled with confidence, hope one day to say to the supreme Arbiter, 'Deign in thy clemency to judge a weak mortal: I have, it is true, done much ill upon earth, but I have published this writing.'" In these letters he again expressed his sentiments concerning revealed religion, in a manner that excited against him great indignation among the clergy of Neuchâtel. A consistory was assembled to take his opinions into consideration, but government interfered to stop its proceedings. The protection of the government was not, however, sufficient to rescue him from the obloquy which the clergy excited against him. They preached against the philosopher, and their sermons excited an uproar among the people. In September 1765, some misguided zealots attacked his house and his person, and he sought an asylum in Bern, which was denied him. Neither the broken state of his health, nor the approach of winter, could soften the hearts of his enemies: he entreated them to shut him up in their common prison, which favour they even denied, and he was under the necessity of setting out on a long journey, in the beginning of a very inclement season; he contrived, however, to reach Strasburg in a very destitute condition. He received from marshal de Contade, who was then commander of that place, every accommodation that could be expected from humanity, compassion, and generosity. Here he waited till the weather became more auspicious, when he set out for Paris, where he appeared in the habit of an Armenian. The celebrated Hume was at  
this

this time a resident in that capital, as chargé d'affaires from the English court, and having been applied to in favour of Rousseau, who was desirous of making England his asylum, he willingly undertook to conduct him thither in the beginning of the year 1766. "At this period," says one of his biographers, "the persecutions which he had undergone, the hostility which he had experienced, and with which he had been hunted from place to place; the acrimony of his numerous opponents, and the ferment which his presence had excited in the different places of his residence, had so agitated his susceptible mind, and inflamed his vanity, that he imagined himself not only the most important, but almost the only important personage in Europe, and fancied that a general confederacy was formed against him of all sects and parties. This notion filled him with absurd suspicions, and rendered him prone to view every thing in a wrong light, and to magnify trifles into matters of great moment. In short, he was under the influence of a perversion of temper and intellect, nearly amounting to mental derangement: a malady which, indeed, in a certain degree, seems to have attended him through life, and which alone can account for his singularities and inconsistencies." Without this clue, his conduct to Mr. Hume must appear the extreme of baseness and ingratitude. This gentleman, sensibly affected with his various misfortunes, procured for him an agreeable situation in England, but Rousseau was not long satisfied with the new place. He had wished for peace, but peace and quiet he was utterly incapable of enjoying. He did not make such an impression upon the minds of the English as he had done upon the inhabitants of other countries. The freedom of his opinions, and the settled melancholy of his temper, were not deemed very remarkable or singular here. He was regarded only as an ordinary man: in the public prints he was satirized; his principles and conduct were represented as quite adapted to a modern Diogenes. He was rather regarded as an object of ridicule than of terror to any of the prevailing parties in England. Rousseau now imagined there was a plot between Hume and the French philosophers to destroy his glory. He sent a letter to him, filled with the most violent abuse, and at the same time refused to accept a pension from the crown, which had been obtained through the interest of Mr. Hume. He did not remain long in England after this, but went to France in the year 1767, where he met with various protectors, with whom he passed his time in different provinces. At this period he published his "Dictionnaire de Musique," which, though an excellent work, brought upon the author much severity of criticism. In the following year he resumed his botanical pursuits, by collecting and studying the plants which he found on the mountains of Dauphiné. In the year 1769, he married a lady with whom he had lived many years, and by whom he had already had five children, all of whom he had safely sent to the orphan hospital. This has been justly esteemed in this country as one of the greatest stains upon his character, though his foreign biographers take little notice of it, and seem to think he was justified by the indigence in which he lived. But how could a man venture to talk of morality, and write upon education, who had abandoned his own children? Notwithstanding his other merits, he must in this respect be held in abhorrence by every feeling mind. During the year 1770, he appeared at a coffee-house in Paris in his ordinary dress, and took much pleasure in the plaudits of the surrounding crowd. Though he affected the love of solitude, yet he was never easy unless he could in some way or other occupy the public attention. He could neither accommodate himself to the world, nor be content to live out of it. Nevertheless, some of

his latter years he seems to have passed more tranquilly than any former period of his life, having, in a good measure, renounced all farther discussion of those controverted topics which had involved him in so many difficulties, and determined to keep his philosophy for his own use. Still he suspected that a confederacy was making against him, and he gladly accepted, in May 1778, an invitation from the marquis de Girardin, to retire with his wife to a small house near his beautiful seat of Ermenonville, where he died in the month of July in the same year, at the age of 66. His friend and patron, the marquis, erected a monument for him in the Isle of Poplars, in his pleasure grounds, with an inscription, to which Rousseau was by no means entitled: "Ici repose l'Homme de la Nature et de la Verité."

After the death of this philosopher, his "Confessions" were published, which give a minute account of every thing that happened to him till the 30th year. This singular piece of biography is itself a striking exemplification of character, for there is hardly any work in which circumstances so degrading and humiliating are related with so little reserve, while the air of importance given to the most trivial incidents in which he was any way concerned, and the contempt of shame implied by exhibiting himself thus naked to the world, prove it to have been dictated more by vanity and self-importance than by contrition. He would have passed for a better man if this work had not been published, but then he could not have had any pretext for talking so much of himself. "His Confessions," says M. Sennequier, author of the Literary History of Geneva, "appear to me a very dangerous book, and paint Rousseau in such colours as we should never have ventured to apply to him. The excellent analyses which we meet with of some sentiments, and the excellent anatomy which he gives of some actions, are not sufficient to counterbalance the detestable matter which is found in them, and the unceasing obliquities every where to be met with." There is no doubt that he has done much mischief to the interests of morality by these "Confessions," as well by the baseness of the vices which he has disclosed, as by the manner in which he united them with the virtues. Among the other pieces of Rousseau, not already noticed, and which were published after his death in a new edition of his works, are, 1. The Reveries of a solitary Wanderer, being a journal of the latter part of his life. In this he confesses that he preferred sending his children into hospitals destined for orphans, than to take upon himself the charge of their maintenance, and endeavours to palliate this shameful dereliction of duty. 2. Considerations upon the Government of Poland. 3. The Adventures of Lord Edward, a novel, being a sort of supplement to his *Héloïse*. 4. Various memoirs and fugitive pieces, with a great number of letters. 5. *Emilia and Sophia*. 6. An opera and a comedy. 7. Translations of the first book of Tacitus' History, &c. &c. Like all the other writings of Rousseau, there are in these posthumous pieces many admirable and useful things; but at the same time they abound with contradictions, paradoxes, and ideas very unfavourable to religion. In his letters especially, we see a man chagrined with misfortunes, which he never attributes to his own want of conduct: he is suspicious of every body about him, calling and believing himself a lamb amidst wolves. All his works are marked with a peculiar warmth and energy of style, and with great vigour of thinking. He was one of the first writers who exercised the greatest influence upon the opinions of the age, and in the early periods of the French revolution, they were referred to as of the highest authority in political matters, and his memory was almost deified. His reputation has since been much in the wane; but as long as the French language

language remains, he must be regarded as one of its great authors. The best edition of his works collectively is in 27 vols. 4to. The principal authorities for the life of Rousseau, independently of his own Confessions, are Sennebler Hist. Lit. de Geneve, and Nouv. Dict. Hist.

In 1768, Rousseau's animated and instructive Musical Dictionary was published, collected chiefly from his musical articles in the Encyclopédie; and as he gave no quarter in it to French music, the admirers and defenders of that music have treated his opinions with equal severity. It is, however, the business of true critics not only to point out the errors of a work, but, if it has any, the merit. There may be mistakes in Rousseau's Dictionary, but are there no good articles, no marks of refined taste and nice observation in speaking of dramatic music? No short, clear, and happy definitions of musical technica? And is every thing he has said of French music thought so absurd and paradoxical at present, even in France, as it was thirty years ago? The abbé Roussier, and his disciple M. de la Borde, who treat as *absurd* and stupid whatever seems unfavourable to their doctrines, were awed perhaps by the thunder of Rousseau's eloquence, while alive; but no sooner were they sure that the lion was dead, than they plucked up a courage, and boldly attacked him at all points.

We must add, in justice to Jean Jacques, that more good taste, intelligence, and extensive views are to be found in his original articles, not only than in any former musical dictionary, but in all the books on the subject of music which the literature of France can boast. And his "Lettre sur la Musique Française," may be safely pronounced the best piece of musical criticism that has ever been produced in any modern language.

It must, however, be confessed, that his treatment of French music is very sarcastic, not to say contemptuous; but the music, the national character *avantageux*, and exclusive admiration of their own music, required strong language. It had been proved long since, that they were not to be laughed out of their bad taste in any one of the fine arts: the national architecture, painting, and sculpture, were, in general, bad, and not what a traveller returning from Italy could bear to look at: though there have been now and then individual French artists of every kind, who have travelled and studied antiquity as well as the great masters of the Italian school; and it is now said, that at the Institute they are trying seriously to correct their errors, and to establish a classical taste throughout the empire.

Yet, after all our sincere encomiums on Rousseau as a musical critic, particularly in the melodrama, and though we subscribe to most of his musical opinions, and defend them, yet we must leave him in the hands of his enemies with respect to Blainville's *new mode*, in recommending which he is totally indefensible. But in the year 1751 he was young in musical theory, and the laws of composition; he had read little, and not studied much; but in 1768, after working so long for the Encyclopédie, in which labour to teach others he must have educated himself, nothing but the state of war between him and the intolerant adherents to Rameau and the old school, could have blinded him so far as not to see the absurdity of Blainville's pretensions to the merit of having invented a new mode, or third key in music, different from the major and minor modes in common use.

It may perhaps be alleged, even by the friends and admirers of his musical writings, that he was more unwilling, than so acute and perspicacious a logician ought to have been, to relinquish his new system of *musical notation*, which he published under the title of "Dissertation sur la Musique moderne," in 1743, when very young, and his knowledge

of music superficial. Forty years had not weaned him from his partiality for this juvenile production; for he not only republished it in 1768, in his Musical Dictionary, but near the end of his life, in 1778, he still persisted in explaining and recommending its adoption: as Fontenelle, at near 100, wrote and published a tract in favour of the Cartesian, and Troubillons against Newton's system of gravitation.

Lord Stanhope, and Mr. Baldwyn of Cheshire, are now (1804) at work on a new method of notation, expressing by letters of the alphabet what Rousseau did by numerical figures, with great confidence of success. But neither Rousseau, nor subsequent ingenious framers of a new musical notation, could or would see the inconvenience and even mischief it would occasion to the art, if ever it was generally adopted, by rendering all former music unintelligible, unless every musician and musical student were at the pains of learning two gamuts, or systems of musical notation, instead of one.

Music is at present an universal language throughout Europe. All nations use the same characters, and write and read them with equal facility. Suppose a tyrant in any one kingdom only, were to insist upon the inhabitants relinquishing at once their native language, and adopting another of which they were utterly ignorant, it is hardly possible to imagine that his mandate would or could be obeyed; but if the despot's will were attempted to be complied with in his particular dominions, would all the rest of Europe burn their books, and set about learning a new alphabet, a new spelling-book, a new grammar, and the art of writing this new language? nothing but its general and universal adoption could render it useful to any one nation upon earth.

ROUSSEL, WILLIAM, a learned French Benedictine monk of the congregation of St. Maur, was born at Conches, a small town within the diocese of Evreux, in Normandy in the year 1658. He became a member of the congregation in the year 1680, and directed his attention principally to those studies which would qualify him for the office of a preacher. Having fine talents, he became very popular, and the general theme of commendation at Paris, but preferring retirement, he withdrew to Rheims, and afterwards to Argenteuil, where he spent the remainder of his life in devotion and study. He died in the year 1717. He published an excellent translation of the Letters of St. Jerome, in 3 vols. 8vo. the first two of which appeared in 1704; and the third, containing the critical letters of that father on the Holy Scriptures, in 1707. They are accompanied with a preface and learned notes. He was author of an *éloge* on father Mabillon. He had employed many years of his life in making preparations for composing "A Literary History of France," but death put an end to his labours, and his papers were placed in the hands of father Rivet, a member of the same congregation, who made use of them without acknowledging his obligation.

ROUSSELAER, in *Geography*, a town of France, in the department of the Lys, situated on the river Mandel; 10 miles S. of Bruges.

ROUSSIER, the *abbé*, in *Biography*, a profound writer on the theory of music, was born at Marseilles in 1716. He is author of a considerable number of musical tracts, of which the following are the titles:

1. A Treatise on Chords and their Succession, 1764.
2. Observations on different Points of Harmony, 1765.
3. Memoir on the Music of the Ancients, 1770.
4. A Letter, in two parts, to the author of the Journal of the Arts and Sciences, concerning the division of the zodiac, 1770. The second part to the same concerning the Institution of the Planetary Week, 1771.

5. Practical Harmony, or Examples in Illustration of the Treatise on Chords, 1776.

6. He was engaged, in 1779, as editor of a memoir on the music of the Chinese, by the abbé Amiot, missionary at Peking. The learned abbé has enriched this memoir with a great number of notes, observations, and a copious index. See *CHINESE Music*.

All this profound writer's treatises are built upon the principles of Rameau, but Rameau sublimed. The abbé's favourite discovery and systematic principle is the triple progression, upon which he endeavours to prove that the musical systems of the Egyptians, Greeks, and Chinese were founded. By triple progression is meant a series of perfect fifths, so that the word temperament equally disturbs his system and his temper. It is to be feared that the good abbé in this particular, and in his principles in general, is too rigid and inflexible a theorist for the fanciful melody, and licentious modulation of modern composers.

The French are always to have champions, *une homme armé*, to combat the music and musical writers of all other countries. At the beginning of the last century, Bonnet was the redoubted champion of the votaries of Lulli in the middle of that century. The abbé Roussier, with less fury, but more intelligence, threw down the gauntlet for Rameau and his *basse fondamentale*; and at the end of the century, the abbé Fautou, the most valourous and invincible of them all, has not only bid defiance to the enemies of Lulli and Rameau, but to the whole universe: a perfect Drawcanfir, that spares nor friend nor foe, who dares be of a different opinion from himself.

ROUSSILLON, in *Geography*, a province of France before the revolution, once belonging to Spain, bounded on the N. by Languedoc, on the E. by the Mediterranean, on the S. by Catalonia, and on the W. by the Pyrenees, about 18 leagues in length, and 12 in breadth, and consisting of land that is generally fertile. Its principal rivers are the Tet and the Tech, and its capital is Perpignan. It now forms the department of the Eastern Pyrenees.

ROUSSILLON, a town of France, in the department of the Isère, and chief place of a canton, in the district of Vienne; 9 miles S. of Vienne. The place contains 963, and the canton 11,107 inhabitants, on a territory of 225 kilometres, in 21 communes.—Also, a town of France, in the department of the Saône and Loire; 9 miles N.N.W. of Autun.

ROUSSIN, in the *Manege*, is a strong well-knit, well-flowed horse, such as are commonly brought into France from Germany and Holland.

ROUSSING, in *Sea Language*, is the act of pulling together upon a cable, hawser, &c. without the assistance of tackles, capsterns, &c. It is particularly used in the exercise of removing a ship from one place to another, by means of ropes and anchors.

ROUT, ROUTE, a public road, highway, or course; especially that which military forces take.

The word is French, *route*, formed from the Latin *rupta*, or *ruta*; or the French *roux*, an old word for *horse*; or rather from the old Celtic *root*, *road*.

Sanfon and Ogilby have made maps of the routs and post-roads of France and England. Soldiers are prohibited going out of their routs. Routts are frequently cut in parks, forests, &c. both for ornament, and for the conveniencies of hunting.

Some use *route* for a path cut across a wood; in opposition to *way*, which is a great road.

ROUT, in *Navigation*. See *COURSE*.

ROUT is also used for the defeat and flight of an army.

ROUT, in *Law*, is an assembly or combination of three or

more persons, upon a common quarrel, going forcibly to commit an unlawful act: such as breaking down fences upon a right claimed of common, or of way, though they do not actually perform it.

If they go, ride, or move forwards, after their meeting, thus making some advances towards the execution of their purpose, it is a rout, though they do not put their purpose in execution; if they do, it is a riot.

A rout, therefore, seems to be an unlawful assembly; and a riot the disorderly fact committed thereby.

Two things, however, there are in common to *rout*, *riot*, and *unlawful assembly*; the one, that there be at least three persons together; the other, that, being together, they disturb the peace, either by words, shew of arms, turbulent gesture, or actual violence.

For the punishment incurred by routs, &c. see *RIOT*.

ROUT of Wolves, among *Hunters*, denotes a herd of those wild beasts.

ROUTIER, in *Navigation*. See *WAGGONER*.

ROUTOÏ, in *Geography*, a town of France, in the department of the Eure, and chief place of a canton, in the district of Pontaudemer; nine miles E. of it. The place contains 1169, and the canton 14,721 inhabitants, on a territory of 110 kilometres, in 21 communes.

ROUTOU, a town of Thibet; 255 miles E.N.E. of Latac.

ROUVRAY, a town of France, in the department of the Côte d'Or; 11 miles S.W. of Semur en Auxois.

ROUVRE, a town of France, in the department of the Upper Marne; 15 miles S.W. of Langres.

ROUVRES, a town of France, in the department of the Vosges; four miles W. of Mirecourt.

ROUVROY, a town of France, in the department of the Somme; 15 miles E. of Peronne.

ROU-WADDE. See *RUAD*.

ROUX, CAPE, a cape of Africa, on the coast of Tunis. N. lat. 37° 10'. E. long. 8° 22'.

ROUXIERE, LA, a town of France, in the department of the Lower Loire; eight miles N.E. of Ancenis.

ROUY, a town of France, in the department of Nièvre; 15 miles E. of Nevers.

ROW, a town of Scotland, in the county of Dumbarton; nine miles W. of Dumbarton.—Also, a town of Hindoostan, in Bahar; 20 miles S. of Bahar. N. lat. 24° 55'. E. long. 85° 52'.

Row-Culture, in *Agriculture*, that method in which the crops are sown in rows or drills, and afterwards cultivated according to that system. See *DRILL Husbandry*.

This sort of cultivation is commonly divided into the narrow and distant kinds, the former comprising all sorts of grain, and some other kinds of crops, which are sown in rows at not more than six, eight, ten, and twelve inches apart; the latter, all those which have large spaces or intervals between the rows, as from a foot to a foot and a half, two feet and more, such as beans, peas, turnips, cabbages, beets, potatoes, carrots, parsneps, and many others. They all require to be wrought between suitable tools, such as hoes and ploughs, at different times, while they are growing upon the ground.

Row-Galley, a long, low, flat-built vessel, furnished sometimes with a deck, and navigated with sails and oars, particularly in the Mediterranean.

ROWAH, in *Geography*, a town of Hindoostan, in Bahar; eight miles N.W. of Bettiah.

ROWALE, or KOWALE, a town of the duchy of Warfaw; 36 miles S. of Wladislaw.

ROWAN, a county of America, and one of the most populous

populous of North Carolina, in Salisbury district; bounded N. by Iredell, and S. by Cabarrus, and containing 21,543 inhabitants.

ROWE, ELIZABETH, in *Biography*, a lady greatly distinguished for her piety and poetical talents, was daughter of the Rev. Walter Singer, a dissenting minister near Frome, in Somersetshire. Under the disgraceful reign of Charles II. this gentleman was imprisoned on account of his non-conformity at Ilchester, where he married, and where his daughter Elizabeth was born in 1674. From her childhood she discovered a passion for reading, together with a devotional turn of mind. At the age of twelve, she began to write verses, and practised music and drawing. Her poetical talents excited notice in the neighbourhood, and gave her an introduction to lord viscount Weymouth, by whose son, the honourable Mr. Thynne, she was instructed in the French and Italian languages. In her 22d year, at the request of her friends, she published a volume of miscellaneous poems, by which she is advantageously known. Possessing an agreeable person, and a large share of the accomplishments of her sex, she attracted the attentions of many admirers, but she appears to have been in no hurry to marry, and it was not till 1710 that she gave her hand to Mr. Thomas Rowe, a very amiable man, a scholar, and a poet, with whom she lived in the enjoyment of a large portion of conjugal felicity. This happiness was not lasting; Mr. Rowe, who was of a consumptive habit, died at Hampstead in 1715, and left his widow overwhelmed with grief, which nothing but her sentiments of pious resignation could enable her to support. From this time she passed her days, for the most part, in retirement at Frome, but making occasional visits to the countess of Hertford. Her manners and attainments rendered her perfectly suited to the best company; and though she adhered to the last to the principles of the Dissenters, she was entirely free both from narrowness of sentiment, and from any forbidding austerity of behaviour. Mrs. Barbauld has, in a few lines, given the manner in which she employed herself, and the persons with whom she associated.

“ Yet in no useless gloom she wore her days,  
She loved the work, and only shunned the praise:  
Her pious hand the poor, the mourner, blest;  
Her image lived in every kindred breast,  
Thynne, Carteret, Blackmore, Orrery approved,  
And Prior praised, and noble Hertford loved.  
Seraphic Kenn, and tuneful Watts were thine,  
And Virtue's noblest champions filled the line.”

Mrs. Rowe composed several works in her retreat, especially those letters from the dead to the living, which her own heavy loss doubtless had suggested. She was blessed with a good constitution, and passed through life with very little interruption of health. She died suddenly in February 1737, in the 63d year of her age. A pious book was found lying open by her, and in her cabinet were found letters to several of her friends, which she intended for them after her death. Her works were, “The History of Joseph,” an heroic poem; “Friendship in Death,” &c.; “Devout Exercises of the Heart;” “Miscellaneous Works,” in two volumes. Few characters have been more justly esteemed than that of Mrs. Rowe. With respect to her poetical works, the general character is correct and melodious versification, flowing language, and tender elevated sentiments. Among her prose compositions the most popular was that entitled “Friendship in Death, in twenty Letters,” supposed to be written from the dead to the living. These are the works of a lively and a feeling heart, exercised in pious meditations, and they are always read with pleasure by the

young, and those who are susceptible of good impressions. They have passed through many editions, and are usually accompanied by other pieces of the author's of a moral and religious kind. All her writings, though not calculated to stand the test of exact criticism, inspire a favourable idea of the writer.

ROWE, THOMAS, the husband of the foregoing, was the son of a dissenting minister, who afforded him all the advantages of an excellent education, and he would probably have become a distinguished literary character, had not his early marriage been followed by a premature death. He wrote some excellent pieces of poetry, one of which was a tender ode to his wife, some years after their marriage. History was his favourite pursuit, and he formed a design of writing the lives of illustrious characters in antiquity, omitted by Plutarch, of which eight were finished, and were published after his death. He died in 1715, at the age of 28. Some of his original poems and translations were printed with Mrs. Rowe's “Miscellaneous Works.”

ROWE, NICHOLAS, an eminent English poet, the son of John Rowe, esq. serjeant at law, was born in 1673, at Little Berkford, in Bedfordshire. After a preliminary education at Highgate, he was placed in Westminster school under the noted Dr. Busby, as a king's scholar, and pursued classical studies with eagerness and success. His poetical exercises in Latin and Greek were particularly admired. He was removed from school at the age of 16, and entered a student in the Middle Temple, and proceeded so far in the pursuit of the law, as to be called to the bar; but the death of his father, when he was only 19, gave him liberty to follow his own inclination, and he devoted himself to poetry and polite literature. At the age of 25 he produced his first tragedy, entitled “The Ambitious Step-mother;” the story of which appears to be founded on that of Solomon elevated to the throne by the machinations of his mother Bathsheba, but the scene and circumstances are totally different. It was acted at Lincoln's Inn-Fields, and was very successful, which is said to have rendered the author a decided deserter from the law. His next dramatic work was “Tamerlane,” which was acted in 1702. This was intended to convey important political impressions: the tyrant and despot Bajazet being intended as the type of Lewis XIV., then considered as the enemy of liberty, civil and religious, and the Tartar Tamerlane was metamorphosed into a perfect prince, intended to characterize the immortal William III. of England. In all the portraits there was much exaggeration, but the purpose of the piece, and its many elevated and liberal sentiments, caused it to be received with great applause. It was frequently acted during that and the following reign, till the year 1710, when different political opinions coming into fashion, it was for a time intermitted, but the accession of the house of Hanover restored it to the stage, and it was for a great number of years represented on the anniversary of king William's landing. In 1703, Mr. Rowe produced his “Fair Penitent,” which is thought to be his most striking piece; it is highly interesting, and abounds with poetry and fine sentiments. Mr. Rowe made an attempt at comedy in 1706, but did not succeed. From this time to 1715, he brought out, in succession, the tragedies of “Ulysses;” “The Royal Convert;” “Jane Shore;” and “Lady Jane Gray.” Of these, the two last have survived on the stage. Jane Shore is now occasionally acted; always when performed engages some of the best actors, and never fails to be viewed with the deepest interest. During this interval he appeared as an editor of Shakspeare's plays, prefixing to this edition an account of the life of that transcendent genius. Rowe was not exclusively engaged in literary pursuits,

he was a man of business, and did not neglect those opportunities of entering into public life, which his reputation and connections afforded. He had joined the Whig party, and when the duke of Queensberry was made secretary of state, he was appointed by that nobleman his under secretary. This post he held about three years, when the duke died, and his services were no more required during the reign of queen Anne. It is said he went, one day, to pay his court to the lord-treasurer Oxford, who asked him if he understood the Spanish language. He replied in the negative, but added, that he did not doubt but he could make himself master of it, supposing his lordship intended to give him employment at the court of Madrid. The earl seemed to approve his intention of studying the language: Rowe took his leave, and retired a few weeks or months to learn it, and then waited on his lordship to acquaint him with what he had done: "then, sir," replied the courtier, "I envy you the pleasure of being able to read Don Quixote in the original," and dismissed him. On the accession of George I. the place of poet laureat was conferred upon him, and he was also made one of the land surveyors of the customs of the port of London. The prince of Wales conferred upon him the clerkship of his council, and the lord chancellor Parker made him his secretary for the presentations. The emoluments of these offices, with his own fortune, enabled him to support a very respectable station in society, but he did not live long to enjoy these accessions to his fortune. He died in 1728, at the age of 45, and was interred among the poets in Westminster-Abbey. Mr. Rowe was twice married, and had a son by his first wife and a daughter by the second. He was a handsome and genteel man; and his mind was as amiable as his person. He lived beloved, and at his death was lamented by Pope, in an epitaph which is to be found in Pope's works, though it is not affixed on the monumental marble at Westminster. Mr. Rowe is chiefly known to the public as a tragic poet; if he does not possess in a very high degree the principal parts of tragic invention, such as the nice discriminations of character, and the skilful development and varied play of passion; his diction is poetical without being bombastic or affected, his versification is singularly sweet, and his plays abound with sentiments, given with such force and elegance as are calculated to dwell upon the mind. In his *Jane Shore* he professes to be the imitator of Shakspeare, but nothing can be more dissimilar than the mode and colour of writing in the two poets, as nothing could be less resembling than their genius. Mr. Rowe is well known also by his poetical translations. He gave versions of the *Golden Verses of Pythagoras*, and of the first book of Quillet's "*Callipædia*," see *QUILLET*; but his chief labour in this way was a translation of Lucan's "*Pharsalia*," which was not published till 1728, ten years after the translator's death, and which Dr. Johnson calls "one of the greatest productions of English poetry;" but if critically compared with the original, it will be found frequently very diffuse. The "*Poetical Works*" of Mr. Rowe, consisting of his plays and miscellaneous poems, were published collectively in three vols. 12mo. in 1719; and his translation of the *Pharsalia* was published soon after his death, with a dedication to the king by his widow.

ROWE, in *Geography*, a township of America, in the N.W. corner of Hampshire county, Massachusetts, bounded N. by Vermont; watered by Deerfield river, and containing 830 inhabitants; 115 miles N.W. of Bolton.

ROWEL, among *Farrriers*, a kind of issue, made by drawing a skain of silk, thread, hair, or the like, through the nape of the neck, or other part of a horse; answering to what in surgery is called a *seton*.

*The ROWELLING of Horses* is a method of cure frequently had recourse to, in cases of inward strains, especially about the shoulders or hips; as also for hard swellings not easily to be resolved.

The operation is thus: a little slit being made through the skin, about a hand's breadth below the part aggrieved, big enough to put a swan's quill in; the skin is raised from the flesh, the end of the quill put in, and the skin blown from the flesh upwards, and all over the shoulder.

Then the hole being stopped by the finger, the place blown is beaten with a hazel stick, and the wind spread with the hand all over, and then let go.

This done, a skain of horse-hair, or red sarfenet, half the thickness of the little finger, is put in a rowelling needle seven or eight inches long; the needle is put into the hole, and drawn through again six or seven inches higher; then the needle is drawn out, and the two ends of the rowel tied together; anointing it every day, as well as before the putting it in, with sweet butter and hog's greafe, and drawing it backwards and forwards in the skin, to make the putrid matter discharge itself more plentifully.

Others, disliking these rowels, as making too great a fore and scar, use the French rowel, which is a round piece of stiff leather, with a hole in the middle, laying it flat between the flesh and skin, the hole of the rowel just against that in the skin; sewing it with a needle and thread drawn through the hole in the skin; cleaning it once in two or three days, and then anointing it afresh.

ROWELS of a *Spur*. See *SPUR*.

ROWEN, in *Geography*, a town of Bohemia, in the circle of Chrudim; 10 miles S.E. of Chrudim.

ROWEN-Tree, in *Husbandry*, a term improperly applied to the mountain ash.

ROWENSKO, in *Geography*, a town of Bohemia, in the circle of Boleslaw; 6 miles S.E. of Turnau.

ROWET, a name sometimes applied to rouen. See *ROUEN*.

ROWETY-WOOL, among wool-dealers, a term applied to the young wool of some sorts of sheep, which rises below the old fleece.

ROWING, is the action of impelling a boat or vessel along the surface of the water by oars, which are managed in a direction nearly horizontal. See *OAR*, *BOAT*, &c.

ROWING-Guard. See *GUARD-BOAT*.

ROWLE, in a *Ship*, is a round piece of wood or iron, in which the whip goes, being made to turn about, that it may carry over the whip the easier from side to side.

ROWLEY, in *Biography*, a monk, who is said to have flourished at Bristol in the 15th century, and whose poems, or those attributed to him, were published, many years ago, by the unfortunate CHATTERTON. See his article.

ROWLEY, WILLIAM, who stands in the third class of dramatic writers, lived in the reign of James I., and was one of the company of players belonging to the prince of Wales. Little is known of him, except that he was in close connection with all the principal wits and poetical geniuses of that age, with some of whom he joined in their writings. By Wood he is styled "the ornament for wit and ingenuity of Pembroke-hall, Cambridge." He was a considerable benefactor to the English stage, having left five plays of his own composing, and lent his assistance to several authors in the composition of many others. The titles of all these are given in the *Biographia Dramatica*; which see.

ROWLEY, in *Geography*, a town of Hindoostan, in Oude; 18 miles S. of Bahraitch.

ROWLEY, a township of America, in Essex county, Massachusetts;

## ROWLEY RAG.

Sachusetts; the inhabitants, amounting to the number of 1682, are mostly farmers; incorporated in 1639, and situated 4 miles N.W. by W. of Ipswich.

ROWLEY Rag, in *Mineralogy*, a basaltic stone from Rowley, near Dudley, in Staffordshire. It is used for polishing in some of the manufactures of Birmingham, and has been particularly recommended for grinding the specula of reflecting telescopes. On this variety of basalt, the fine-grained grunstein of Werner, some most interesting experiments were made by the late Mr. Gregory Watt, to determine the important question respecting the igneous or aqueous origin of basaltic rocks. Perhaps few experiments in the last fifty years throw more light on some of the mysterious operations of nature in the mineral kingdom, and have a better claim to the profound attention of philosophers, or are more deserving of being repeated and diversified. (See *Phil. Trans.* for 1804, p. 279.) Before a short account of these experiments, it may be proper to give a description of the stone itself. Rowley rag is a species of fine-grained basalt, of a confused crystallized texture; its fracture, in small pieces, is uneven; in the large, conchoidal. Its hardness is superior to common glass, but inferior to felspar; its tenacity is considerable; its action on the magnetic needle is strong, but without signs of polarity; its specific gravity is 2.868. The general colour of Rowley rag is a very dark grey, approaching to black: it reflects light from a variety of brilliant points, some of which seem to be felspar, the others hornblende. According to the analysis of Dr. Withering, 1000 parts contain 475 flux, 325 argillaceous earth, and 200 of the oxyd of iron. The magnetic property of these rocks was first observed by Dr. Plott, who says they turned the needle 6° from its proper direction. The same power of affecting the magnet has since been discovered in several basaltic mountains, particularly in the Giant's Causeway in Ireland. This stone is similar to the basalt of the Cleve hills, in Shropshire, and the basaltic stones in various parts of Great Britain. In its characters and chemical composition it nearly resembles some of the compact lavas from *Ætna* and *Teneriffe*. It is easily fusible into an opaque black glass, which, however, transmits light through very minute fragments. The texture of this glass is completely vitreous, with a few air-bubbles. Its fracture is conchoidal and undulated; the hardness is superior to felspar, but inferior to quartz. This glass possesses scarcely any action on the magnetic needle. The specific gravity is 2.749.

For the purpose of ascertaining the effect of a high degree of temperature on a considerable quantity of this stone, one of the common reverberatory furnaces, used in iron foundries for the fusion of pig-iron, was strongly heated by a fire maintained several hours. About seven hundred-weight of amorphous Rowley rag was broken in small pieces, and deposited gradually on the elevated part of the interior of the furnace, between the fire and the chimney; from whence, as it melted, it flowed into the deeper part, in which, in ordinary operations, the iron is collected. It was observed by the persons attending, that it did not require half the quantity of fuel to fuse the basalt that would have been necessary to melt an equal weight of pig-iron. When the whole was melted, it formed a liquid glass, rather tenacious, from which a large ladleful was taken, which, being allowed to cool, retained the characters of perfect glass. The fire was maintained, though with gradual diminution, for more than six hours; after which time, the draught of the chimney was intercepted, the surface of the glass was covered with heated sand, and the furnace was filled with coals, which were consumed very slowly. It was eight

days before the mass in the furnace was sufficiently cool to be extracted, and even then it retained considerable heat.

The form of the mass being given by the bottom of the furnace, approached to the shape of a wedge. It was nearly three feet and a half long, and two feet and a half wide; about four inches thick at one end, and above eighteen inches at the other. Owing to this inequality of thickness, and also to the unequal distribution of heat in the furnace, Mr. Watt states that the cooling of the mass had been too irregular to permit it to attain an homogenous texture; but this circumstance fortunately disclosed some very remarkable peculiarities in the arrangement of the particles of bodies, passing from a vitreous to a stony state.

These peculiar changes were discovered, by inspecting the various parts of the wedge-shaped mass, which had progressively cooled, as they were more remote from the fire, and nearer to the small extremity. This circumstance, not being very distinctly stated by Mr. Watt, has led some of the readers of the paper to believe that the changes were observed by taking a portion of the substance out of the furnace at different times, during the process: hence they have not sufficiently attended to a most important fact which this experiment discloses, namely, that the particles of bodies in a solid state, and at a temperature much below that of fusion, are capable of a kind of internal motion, and of assuming a crystalline arrangement, in all the various stages from fluidity to a perfectly solid state.

The tendency towards arrangement in the particles of the fluid glass is first developed by the formation of minute globules, which are generally nearly spherical, but sometimes elongated, and which are thickly disseminated through the mass. The colour of these globules is considerably lighter than that of the glass; they are commonly greyish-brown, sometimes inclining to chocolate-brown; and when they have been formed near the interior surface of the cavities in the glass, they project and resemble a cluster of small seeds. Their diameter rarely exceeds a line, and seldom attains that size; as, in general, they are so near to one another, that their surfaces touch before they can acquire considerable magnitude. In the process of cooling, they adapt their form to their confined situation, fill up every interstice, and finally present a homogenous body, wholly unlike glass, and equally unlike the parent basalt. When the union of the little globules has been imperfectly effected, the fracture of the mass indicates its structure, by numerous minute conchoidal fractures, which display the form of each globule. But if the arrangement has extended a little farther, all these subdivisions are entirely lost; the mass becomes perfectly compact, has an even or a flat conchoidal fracture, is nearly of the same hardness as the glass, is commonly of a chocolate colour, graduating into a brownish-black, and the intensity of the colour increases in proportion to the degree to which the arrangement has extended. Its aspect is rather greasy; and it much resembles some varieties of jasper, in the compactness of its texture, and its opacity. Its magnetic action is extremely feeble. Its specific gravity appears to be 2.938. From this resemblance to jasper, Mr. Watt denominates the mass in this state jaspideous.

If the mass were now rapidly cooled, it is obvious, says Mr. Watt, that the result would be the substance I have just described; but if the temperature adapted to the farther arrangement of its particles be continued, another change is immediately commenced; by the progress of which it acquires a more stony texture, much greater tenacity, and its colour deepens as these changes advance, till it becomes absolutely black. Sometimes this alteration is effected

## ROWLEY RAG.

effected by a gradual transition, the limits of which cannot be assigned; but more generally by the formation of secondary spheroids, in the heart of the compact jaspideous substance. These spheroids differ essentially from those first described: the centres of their formation are more remote from each other, and their magnitude is proportionably greater, sometimes extending to a diameter of two inches, and seeming only to be limited by contact with the peripheries of other spheroids. They are radiated with distinct fibres: sometimes the fibres resemble those of brown hæmatites, and sometimes they are fasciculated irregularly, so as to be very similar in appearance to the argillaceous iron ores, rendered prismatic by torrefaction. They are generally well defined, and easily separable from the mass they are engaged in; and often the fibres divide at equal distances from the centre, so as to detach portions of the spheroid in concentric coats. The transverse fracture of the fibres is compact and fine-grained; the colour black; and the hardness somewhat inferior to that of the basaltic glass. When two of the spheroids come in contact by mutual enlargement, no intermixture of their fibres seems to take place: they appear equally impenetrable; and as neither can penetrate, both are compressed, and their limits are defined by a plane, at which a separation readily takes place, and each of the sides is invested with a rusty colour. When several spheroids come in contact on the same level, they are formed by mutual pressure into pretty regular prisms, whose division is perfectly defined; and when a spheroid is surrounded on all sides by others, it is compressed into an irregular polyhedron.

The transition from this fibrous state to a different arrangement, seems to be very rapid, for the centre of most of the spheroids becomes compact before they attain the diameter of half an inch. As the fibrous structure propagates itself by radiating into the unarranged mass, the compact nucleus, which supplies its place, gradually extends till it finally attains the limits of the spheroids; and the same arrangement pervades the matter comprehended between them. The mass has now assumed a compact stony texture, and possesses great tenacity. Its hardness is somewhat inferior to that of the glass from which it was formed. Its action on the magnetic needle is very considerable. Its specific gravity is 2.938. Its colour is black, inclining to steel grey; it is absolutely opaque, and only reflects light from a few minute points. Though the divisions between the spheroids are rendered imperceptible to the eye, they are not obliterated, and their rusty surfaces are often disclosed by an attempt to fracture the mass.

A continuation of the temperature favourable to arrangement speedily induces another change. The texture of the mass becomes more granular, its colour rather more grey, and the brilliant points larger and more numerous; nor is it long before these brilliant particles arrange themselves into regular forms; and finally the whole mass becomes pervaded by thin crystalline laminae, which intersect it in every direction, and form projecting crystals in the cavities. The hardness of the basis seems to continue nearly the same; but the aggregate action of the basis and of the imbedded crystals on the magnetic needle, is prodigiously increased. It appears to possess some polarity, and minute fragments are suspended by a magnet. Its specific gravity is somewhat increased, as it is now 2.949. The crystals contained in it, when examined by a microscope, appear to be fasciculi of slender prisms, nearly rectangular, terminated by planes perpendicular to the axis; they are extremely brilliant, but their colour is greenish black; they are harder than glass, and fusible by the blowpipe; they are suspended by the action of a magnet.

They are arranged nearly side by side, but not accumulated in thickness, so that they present the appearance of broad thin laminae; they cross one another at all angles, but always on nearly the same plane; and the laminae thus formed are often three or four lines long, and from a line to a line and a half broad, but extremely thin.

It seems obvious that an equalized temperature would have rendered the whole similar to the substance last described; and it may be fairly inferred, that by a continuance of heat the minute crystals would have been augmented in their dimensions by the accession of similar particles still engaged in the basis, or by the union of several crystals, till they acquired sufficient magnitude for their nature to be absolutely determined by the usual modes of investigation. It is possible, however, if such precautions had been taken as might have secured this degree of perfection in the ulterior result, that the mass would only have exhibited an uniform aspect, and that the interesting initial phenomena would not have been discovered.

The appearances here described seem deserving of consideration in several points of view. Few things can be more at variance with commonly received opinion, than the diversified succession of changes of structure which this glass exhibits in its passage to a crystallized state. The generation of the globules which unite to form the jaspideous substance, is what we might be prepared to expect by observing the cooling of a common iron furnace slag. But it appears not very obvious to common apprehension that the species of arrangement requisite to form this intermediary substance, could be compatible with any fluidity permitting farther motion of the ultimate particles of the mass; yet immediately after the completion of this arrangement, they receive a new disposition, and the radiated fibrous structure commences. Sometimes this pervades even the unaltered glass; but Mr. Watt presumes this only to happen where the minute globules first formed were scattered so far asunder that their centres became fibrous before their peripheries came into contact. This view of the subject is justified by the analogous operation of the formation of crystals similar to those described in the heart of the radiated spheroids, while their exterior still retained the fibrous texture.

If it be considered as extraordinary that a change should be effected, converting an apparently solid and homogeneous mass into an accumulation of radiated spheroids, and that these radii should lose their fibrous structure, and assume the texture, aspect, and tenacity, of a compact, hard, and homogeneous stone, it is certainly much more extraordinary that this stone should permit farther arrangement to proceed, and should enable the crystalline molecules which it contains in a state of confused aggregation, to arrange themselves, and to form regular crystals, which, although minute, are equal, in the perfection of their forms, and in the brilliancy of their natural polish, to the most precious products of crystallization. It is also well deserving of observation by how regular a march the magnetic influence of the substance keeps pace with the perfection of its arrangement, till it becomes so powerful that fragments of the regenerated stone are suspended by the magnet.

It has been most justly remarked by Mr. Smithson, that solution, far from being necessary to crystallization, effectually prevents its commencement; for while solution subsists, crystallization cannot take place. It may remain a question whether previous solution be essential as a preparatory means of obtaining, by subsequent evaporation or cooling, the small parts of bodies disengaged, so that they may unite to form regular crystals. If, by solution be only meant that simple action of heat, or water, which merely counteracts

teracts the force of aggregation, and relieves the molecules from their bonds of union with each other, it certainly is a requisite; but if by solution be meant that action of affinities, by which not only the force of aggregation is overcome, but the combinations which constitute the molecules are destroyed, it obviously is not only unnecessary, but prejudicial, to crystallization. Mechanical suspension in a fluid medium of such density that the crystalline polarity may be enabled to counteract the power of gravity, is, with justice, considered by Mr. Smithson the only requisite for the formation of crystals. The circumstances here detailed appear an additional confirmation of this remark, and perhaps go still farther, by shewing that even the fluidity (in the common sense of the word) of the suspending medium is not an indispensable condition. For it appears impossible to annex the idea of fluidity to the union of the minute globules which form the jaspideous substance, still less to that substance when formed, or to those spheroids whose obstinate impenetrability is so strongly defined. And if, by any power of imagination, these can be supposed to be fluid at the time they retain this conformation; how can it be supposed that the compact, hard, tenacious stone into which they are changed, could retain these characters in a fluid state? Yet the subsequent formation of crystals proves that either all these contradictions must be, or that the particles of bodies apparently solid, must be capable of some internal motion, enabling them to arrange themselves according to polarity, while they are solid and fixed, as far as they have reference to the ordinary characters of fluidity.

Instances, even more remarkable, of the motion of the particles of bodies in a solid state, have very long been known and authenticated, though perhaps they have not been generally regarded with the attention they deserve. Glass vessels are well known to be convertible into Reaumur's porcelain by the internal arrangement of their particles without losing their external form, and consequently at a temperature very much below that requisite for their fusion. The change of glass into Reaumur's porcelain does not arise from an evaporation of the alkali, as has been alleged, but from a regular arrangement of the particles of the glass. It commences by the formation of fibres perpendicular to the surface of the glass, and penetrating into it. At nearly the same time small radiated globules are formed in the interior of the glass, and the union of these with the fibres, by their mutual increase, forms the whole into a new substance; and if the requisite temperature be longer maintained, the fibres disappear, and the whole becomes fine-grained and almost compact. This substance, from the improved state of its aggregation, is much stronger and more tenacious than before, and is not fusible at a heat sufficient to fuse the glass it was formed from; but if that aggregation be once destroyed, the glass resulting from its fusion is equally fusible with the original glass; and a repetition of the process will again form Reaumur's porcelain, which may be again fused, and so on repeatedly; for the quantity of alkali evaporated during the operation is extremely small. The hardness and brittleness of metals rapidly cooled, contrasted with the softness and tenacity resulting from their gradual refrigeration, are all analogous instances; and all the processes in which annealing is employed, and more remarkably the tempering of steel, offer strong proofs of the internal motions and arrangements of the particles of matter at temperatures very much below the heat requisite for their fluidity. Mr. Watt further adduces the structure and texture of calcareous stalactites as offering proofs of the internal motion of the particles of solid bodies at the common temperature of the atmosphere. Successive depositions of cal-

careous carbonate form a stalactite which at first is fibrous. A continuance of the process causes the fibrous structure to disappear, and the stalactite becomes irregularly crystalline. The irregularities afterwards vanish, and it becomes perfect calcareous spar, divisible into large rhomboids, with the form peculiar to that mineral, and all the gradations may be found in the same specimen. For a more particular account of these experiments, and the ingenious observations of Mr. Watt, we must refer the reader to the volume of the Philosophical Transactions above cited. The proofs and illustrations of the arrangements which take place in the internal particles of solid bodies, offer the only plausible explanation, which has yet been given, of the formation and decomposition of crystals under various circumstances in which they occur in mineral veins, and also of the prismatic forms observable in currents of lava, and in basaltic and other rocks. See TRAP, and VOLCANIC PRODUCTS.

ROW-LOCKS, among *Ship-Carpenters*, small spaces left in the gunwale, where two thools are let in, at such a distance from each other, as to admit the oar, at the end of the loom, to lie on to row the boat.

In the sides of the smallest vessels of war, a number of little square holes, called *row-ports*, are cut for this purpose parallel to the surface of the water.

ROWNING, JOHN, in *Biography*, an English mathematician and philosopher of considerable ingenuity, was fellow of Magdalen college, Cambridge, and afterwards rector of Anderby, in Lincolnshire. He was chiefly known for mechanical contrivances and inventions. In 1738 he published a compendious system of natural and experimental philosophy, in 2 vols. 8vo. which was frequently referred to thirty or forty years ago, and which has passed through many editions, but is now superseded by many other similar works of more value. He has likewise two pieces in the Philosophical Transactions, one containing a description of a barometer, in which the scale of variation may be increased at pleasure; the other, giving directions for making a machine for finding the roots of equations universally. He published likewise "A Preliminary Discourse on the Fluxionary Method." Mr. Rowning, died in November 1771, in the 72d year of his age.

ROWS of Trees. See PARALLELISM.

ROWSING, in *Sea Language*, denotes pulling upon a cable or rope, without the assistance of capterns, &c.

ROWT, in *Rural Economy*, a term signifying to low as cattle.

ROWTEE, in *Geography*, a town of Hindoostan, in the circle of Sumbul; 15 miles S.S.W. of Nidjibabad.

ROWTOMPOUR, a town of Hindoostan, in Oude; 16 miles S.S.W. of Kairabad.

ROWTY, in *Agriculture*, a term signifying over-rank, or too strong.

ROXBOROUGH, in *Geography*, a township of Philadelphia county, in Pennsylvania.

ROXBURGH, a village in Roxburghshire, Scotland, was formerly a place of considerable importance, as may be conjectured from the circumstance of its having given name to the county. It was for several centuries a royal burgh; and was regarded as one of the first towns in the Scottish kingdom, for opulence, and magnificence of appearance. It was totally destroyed by king James II., and never afterwards recovered; and as its site is now converted into arable fields, the plough has nearly obliterated all traces of its existence. Some remains of its ancient castle, however, are yet visible about two miles eastward from the village. These

These occupy the summit of a bold eminence, which rises from the plain, near the junction of the Tweed and the Teviot. This fortress, in ancient times, was of great strength, and was accounted the most important strong-hold on the Scottish borders. It was environed by a deep ditch, which could be filled at pleasure by the garrison with the waters of the Teviot, and over which a drawbridge was thrown. Interior to the ditch was a wall, of which only a few fragments are standing, but enough to attest its prodigious thickness and solidity. Roxburgh castle, Pennant informs us, in his Tour in Scotland, was anciently called Marchidon, Marchmont, or the Hill on the Marches. The name of its founder is unknown, as is the period of its erection. The earliest mention of it in history occurs in 1132, when a treaty of peace is stated to have been concluded here, between king Stephen of England and king David I. of Scotland. In 1174, after king William the Lion was made a prisoner by the English, this castle, with four others, was delivered up to king Henry II. as a security for his royal hostage doing homage for his crown on his release from captivity. The successor of Henry restored it to the Scots, but it was again taken by king Edward I. in 1296. It was recovered doubtless by king Robert I., but appears to have been soon after possessed by the English, as it is recorded to have been surprised, in 1342, by sir Alexander Ramsay, who was appointed governor; an honour which the envious Douglas did not allow him to enjoy long. The Scots again lost this fortress in the reign of Edward III., who twice celebrated his birth-day here. After this period it was taken and retaken several times; but the most distinguished siege was that by king James II., when it was captured by the Scots; though, previous to the victory, the king was killed by the bursting of a piece of ordnance. A hollow tree is said to stand on the spot where the monarch fell, on the north side of the Tweed, and at a short distance below Fleur's house. The queen, who was with the army when this event took place, observing that the soldiers were disheartened, and that the commanders were disposed to raise the siege, used every exertion to excite their courage; and, among other things, told them, that though their king had fallen, he was but one man, and that she would soon give them another king, her son, James III., who next day arrived in the camp, and was crowned at Kelso, in the 7th year of his age. This heroic and well-timed address produced the desired effect; the spirits of the whole army were roused, and the attack having been renewed with redoubled ardour, the garrison surrendered in a few days. From that period the castle has remained in ruins, though it was in some degree repaired by the lord protector, Somerset, in the reign of Edward VI. of England.

The parish of Roxburgh extends eight miles in length, and about four in breadth. The general appearance is flat and sloping, and the soil is generally a rich loam, well calculated, either for the growth of wheat, or for the turnip husbandry. According to the parliamentary returns of 1811, it contains 225 houses, and 946 inhabitants. The Statistical Account of Scotland, by sir John Sinclair, bart. vol. x. 1797. Pennant's Tour in Scotland, vol. iii. 4to. 1779. Beauties of Scotland, vol. ii. 8vo. 1805.

ROXBURGHIA, in *Botany*, received that name, at the suggestion of the right honourable sir Joseph Banks, from the pen of the late Mr. Dryander, in just commemoration of the discoverer of this genus, Dr. William Roxburgh, F.L.S., member of the Asiatic Society. The researches of this indefatigable and enthusiastic observer of nature, among the botanical treasures of Hindoostan, and his liberal communications to his friends at home, have added very extensively

to our knowledge of Indian plants. The East India Company have published his *Coromandel Plants* in a style worthy of the materials. From the remote situation of the author, many genera and species were left by him for the determination of his learned editor, to whom all the sources of literary information in Europe were open. But as the name of this editor is entirely kept out of sight, a French writer, De Theis, has been led into the mistake of charging Dr. Roxburgh with the unexampled arrogance of dedicating a genus to his own honour. No man can be further, than our candid and unassuming friend, from such presumption, and we feel it a duty to wipe away the unmerited reproach.—Dryand. in Rox. Coromand. v. 1. 29. Willd. Sp. Pl. v. 2. 321. Ait. Hort. Kew. v. 2. 347. Sm. Exot. Bot. v. 1. 111.—Class and order, *Tetrandria Monogynia* (*Oxandria*; in Hort. Kew.) Nat. Ord. *Sarmentacea*, Linn. *Asparagi*, Juss.

Gen. Ch. *Cal.* none, unless the corolla be taken for such. *Cor.* Petals four, inferior, lanceolate, equal, ribbed, coloured chiefly on the upper side, permanent. *Stam.* Filaments four, opposite to the petals, and nearly as long, awl-shaped, fleshy, with a double cell at their inner side, near the base; anthers two-lobed, oblong, lodged in the cells of the filaments, and each crowned with a simple lanceolate appendage, much shorter than the naked summit of the filaments. *Pist.* Germen superior, small, sessile, ovate; style none; stigma roundish. *Peric.* Capsule of one cell, with two concave valves. *Seeds* numerous, erect, cylindrical, furrowed, each supported on a stalk clothed with little vesicles.

Ess. Ch. Petals four, spreading. Filaments lanceolate, keeled, bearing the anthers on their inside, near the base, crowned with an appendage. Capsule superior, of one cell, with two valves, and many seeds.

1. *R. viridiflora*. Green-flowered Roxburghia. Sm. Exot. Bot. v. 1. 111. t. 57. (*R. gloriosoides*; Dryand. in Ait. Hort. Kew. v. 2. 348. Roxb. Coromand. v. 1. 29. t. 32? *R. gloriosa*; Curt. Mag. t. 1500. *Ubiun polyoides album*; Rumph. Amb. v. 6. book 9. 364. t. 129.)—Native of low moist woods and thickets in the valleys of Hindoostan and Amboyna, flowering in the cold season. Roots being sent by Dr. Roxburgh to the late lady Amelia Hume, they bore flowers in April 1805, for the first time in Europe. Each root consists of many oblong fleshy knobs. The *stem* climbs spirally to the height of many feet, without tendrils, and is branched, angular, smooth and leafy. Lower leaves alternate to the height of five feet, the rest opposite; all spreading, on smooth, channelled footstalks, ovate or partly heart-shaped, pointed, entire, smooth, thin and pliable, with about seven or nine ribs, and innumerable fine transverse veins. *Stipulas* none. *Flower-stalks* axillary, solitary, shorter than the leaves, smooth, deflexed, racemose, each bearing two, three, or four flowers. *Bractææ* lanceolate, solitary, under each partial stalk. *Flowers* ascending, large, fetid like corrupted water, or the Stinking Morel. (See PHALUS.) *Petals* near two inches long, coriaceous, green, with purplish ribs, especially on the upper side. *Stamens* violet in the lower part; their points green. The *pollen*, consisting of highly polished globules, falls to the bottom of the flower, rolling about like quicksilver.

The figure given by Dr. Roxburgh differs from our plant, in having much smaller flowers with tawny petals, and yellow anthers. He thinks it likely that there may be more than one species of this genus, which he did not distinguish in India. Rumphius describes two, his *Ubiun polyoides album* and *nigrum*. The former seems best to agree with our plant, except that his figure has solitary flowers. He says its stems extend to the length of 100 fathoms, and that the

*roots*, previously prepared with lime-water, are candied with sugar, and taken with tea. Their flavour is insipid.

Our friend Dr. Sims, in Curtis's Magazine, while he follows the ideas of preceding authors respecting the characters and affinities of this singular plant, avows a preference for the very different view which we have taken; and we derive much confidence from his sanction. It is to be regretted, that, with the best possible intention, he has been misled by the French botanists, to change a faulty specific name much for the worse. The word *gloriosa*, whether designedly or not, serves but to perpetuate their unjust ideas of Dr. Roxburgh, as having, by an unexampled instance of *vain-glory*, inscribed a genus to himself. We most wonder at Dr. Sims's continuing to apply a specific name which, by his own confession, appears to belong to a different plant, whose flowers are "hardly half the size." For this, the original species, we would, as the least evil that presents itself, retain the name of *gloriosiformis*, which is at least correct, and very expressive. We had long ago detected Rumphius's synonym. It agrees best with our *viridiflora*.

**ROXBURGHSHIRE**, in *Geography*, one of the southern counties of Scotland, is situated between N. lat.  $55^{\circ} 7'$ , and  $55^{\circ} 42'$ , and between W. long.  $1^{\circ} 39'$ , and  $2^{\circ} 36'$ , from the meridian of London. It is bounded on the south by Cumberland and Northumberland, in England; on the east by the latter county only; on the north and north-east by Berwickshire; and on the west and north-west, by the counties of Dumfries, Selkirk, and Midlothian. In point of shape, it is so extremely irregular, that it is difficult to define its extent. Its greatest length, from the junction of the Mare-burn with the Liddel, to the junction of Carham-burn with the Tweed, is 41 miles; and its greatest breadth, on a line intersecting the above at right angles, is 29 miles. Its medium length is about 30, and its medium breadth a little more than 22 miles, making its contents about 672 square miles, or 430,080 square acres; of which, at the time of the last survey, in 1796, nearly three-fifths were in sheep pasture, and the remainder in arable cultivation, or occupied by woods, pleasure-grounds, towns, and villages. Politically speaking, this county comprehends twenty-nine entire parishes, and a portion of five others, which, united, contain, according to the parliamentary returns of 1811, 6518 houses, and 37,230 inhabitants.

*Historical Events*.—To narrate all the military transactions which history and tradition affirm to have occurred within this county, would be to occupy our pages with an almost endless detail of petty conflicts and depredatory excursions. Roxburghshire being a border district, and uniting, for above 60 miles, with England, was, for several centuries, a perpetual scene of border warfare; so that there is scarcely a spot throughout its whole extent, where some feat of valour, or deed of destruction, has not happened. Every parish presents, to the discerning eye of the antiquary, some relic of those wretched days when the restraints of law were set at defiance, and rapine and butchery constituted the chief delight both of the lord, and of his vassal peasantry. Of those events which do not bear the character of predatory warfare, the most prominent are the siege of Roxburgh castle, by king James II., before-mentioned, and the battle of Jedburgh, in which the Scots were completely defeated by the English under the earl of Surrey. The latter event happened in the year 1523.

*General Aspect of the County*.—The surface of Roxburghshire is finely diversified, and exhibits many scenes that are truly beautiful, but few that are romantic or sublime. It is commonly considered as divided into four natural districts; Hawick, Jedburgh, Kelso, and Melrose. Of these, the

district of Hawick is the most mountainous; and there is also a chain of hills along the southern boundary of the county. The other divisions present to the eye a succession of hills and vallies. The hills have mostly sloping sides, and are covered with a green sward to their very summits. Very few of them are bleak, and none of them rugged or tremendous. The prospects from their highest points are extensive, variegated, and delightful. The numerous vales, whether of narrow, or of wide extent, are all watered by limpid streams; many of them naked, and others fringed with wood. Some afford excellent pasture, and others are in high cultivation. They are in general inclosed by very gentle declivities, though several are hemmed in by steep banks, over-run with brush-wood, or adorned with lofty trees, which form a scenery rather agreeable than magnificent. In a county so extensive, and, on the whole, so much elevated, the proportion of heath and moss is very inconsiderable, but cannot be calculated with any degree of exactness, as they are scattered every where in portions of unequal size. In Liddesdale, where improvement has made the least progress, patches of moss are seen by the edges, and even in the middle of fertile vales. There are indications of this having been formerly the case in other parts of the county, on which industry has now wrought a happy change.

*Mineralogy*.—Roxburghshire derives little importance from its mineral products. Coal has been discovered in several places, but is wrought only in one spot, near the southern extremity of the district of Liddesdale. Hence the county labours under the serious disadvantage of a want of fuel, which must be brought from Northumberland, or Midlothian, by land-carriage. Throughout the whole shire lime-stone is abundant, but little of it is calcined for sale, except in the neighbourhood of the Liddesdale collieries. Free-stone also is plentiful. The principal stratum extends in a north-east direction from the farthest point of Liddesdale to the neighbourhood of Spronfoun, where it is of a fine, hard, and durable nature. Different kinds of whinstone appear every where on the surface, in the beds of brooks, and in inexhaustible quarries. Vast beds of shell marle lie scattered throughout the contiguous parishes of Robertson, Ashkirk, Wilton, Minto, Lilliesleaf, Bowden, Galashiels, and Selkirk. There are likewise large marle pits at Eckford and Ednam; and some less considerable ones in various places. Pebbles are found in vast multitudes in the vicinity of the Cheviot hills. In the parish of Heb-kirk, there is a place called Robert's Linn, where there are large rocks of pebbles, which are manufactured into seals and buttons of various kinds. Most parts of these rocks are of a light blue colour; but some portions of them are finely varied with streaks of red and yellow; and so much are they esteemed, that great numbers of them are conveyed to Sheffield, Birmingham, and other towns.

*Rivers, &c.*—No county in Great Britain can boast of more numerous, or more beautiful rivers and brooks. One flows through, and enlivens every little vale. The principal of them are, the Teviot, the Jed, Tweed, Rule, Kale, Oxnam, Gala, Slittridge, Ale, Calla, Borthwick, Ednam, Bowmont, Allan, Leader, Ettrick, Hermitage, and Liddel. The two last are discharged into the Elk, which runs into the Solway frith; the others fall into the Tweed, which empties itself into the sea. This river holds a majestic course along banks which, in several places, are steep and bold, jutting out, at Old Melrose, into a promontory, and forming around Dryburgh abbey a peninsula. It partly bounds, and partly intersects, the county; receiving on the north the Gala, which is the boundary with Selkirkshire and Midlothian for five miles; the Leader, which, for nearly

## ROXBURGHSHIRE.

the same space, is the boundary with Berwickshire; the Allan, a pastoral rivulet; and the Eden, which takes its rise in Berwickshire, but runs a considerable way along the skirts, and through the lower district of this county. Ettrick, also a boundary of Selkirkshire for two miles, falls into the Tweed on the south. Teviot rises in the western part of the county, in a very elevated district, and descends at first from the mountains with a rapid course; but it afterwards flows with many delightful windings through a succession of rich, extensive, and well cultivated vallies, till it loses itself in the Tweed between Roxburgh castle and Kelfo, one of the most enchanting spots which can be well imagined. The Ale and Borthwick are the northern branches of Teviot. Both of them have their sources in Selkirkshire, and in some places bound that county and Roxburghshire. On the south the Teviot is augmented by the Oxnam, the Jed, and the Kale. The two last issue from the border hills. The Kale frequently overflows the greater part of an expanded and valuable plain, adorned by clumps of trees; while the Jed, rushing along a rocky channel, through narrow and thick wooded vales, washes the bottom of several high precipices, winds round the town of Jedburgh, and terminates another, and still more extensive plain, called Crailinghaughs, through the centre of which the Oxnam finds its way to Teviot. Nearer to its source, the last-mentioned river receives the Rule, the Slittridge, and the Allan, all of which rise on the confines of Liddesdale. In the number and value of its trees, Rule may vie with "Silvan Jed," though not in wild and picturesque scenery. Slittridge is not without the beauties of green hills, natural wood, and hollow vales. Southern Allan, like the stream of the same name north of Tweed, flows entirely through sheep-walks. Bowmont, also a pastoral river, has its source in the south-east district of the county, and after a rapid course of nine or ten miles, enters England. But of all the waters in Roxburghshire, none are more indebted to nature, or might be more improved by art, than Hermitage, which rises in the southern declivity of the same ridge, whence the Allan and the Slitridge issue in different directions, and tumbling over a bottom of rough, shapeless stones, amidst green hills, whose bases are generally skirted with copse-wood, loses itself in the Liddel, and imparts its natural ornament to that larger stream which is celebrated by Armstrong in the following strains:

"————— Such the stream  
On whose Arcadian banks I first drew breath,  
Liddel, till now, except in Doric lays,  
Tun'd to her murmurs by her love-sick swains,  
Unknown in song; tho' not a purer stream  
Through meads more flowery, more romantic groves,  
Rolls towards the western main. Hail sacred flood!  
May still thy hospitable swains be blest  
In rural innocence; thy mountains still  
Teem with the fleecy race; thy tuneful woods  
For ever flourish; and thy vales look gay  
With painted meadows, and the golden grain."

There are no lakes of any great extent in this county, but there are several pre-eminent for the beauty of their scenery, and the abundant supply of fine perch and pike which they contain. Alcmuir-loch, which ranks first among the Roxburghshire lakes, is somewhat more than two miles in circumference. Trouts of various sizes and flavour abound in all the rivers, and the Tweed and Teviot, but particularly the former, are crowded with grilse and salmon.

*Climate.*—In a county of such extent as Roxburghshire,

the climate must of course be extremely various. In proportion to the elevation of the ground, the air is more moist and sharp. The warmest and driest months of the year are July and August, but prodigious thunder showers are very frequent. In September and October the weather admits of every possible variation. It is often serene and pleasant; but excessive rains, winds, and frosts, and even hail and snow, are by no means uncommon; and frequently do incredible damage to the crops. November is nearly of the same complexion; and what seems singular, in December the weather in general is moderate and uniform. Frost and snow are seldom severe or of long duration before Christmas. January and February are the months when snow is most common, and frost most intense. With some short interruptions they very frequently remain till dissipated by the sun in March. Cold easterly winds prevail much in April and May, and often even in June, either bringing constant rain for a succession of days, or exhaling moisture so rapidly from the earth, as to flint the tender stalks both of corn and grass. But these assertions, though generally true, are at times reversed. After an open and soft winter, great quantities of snow have fallen in March, April, and May. In other years April has been wonderfully mild, May and June the warmest, July and August the wettest, and September and October the most settled months.

*Soil.*—In the pasture district of Roxburghshire the soil is dry, wet, or heathy. To the eastward of Jed Water, the hills are chiefly composed of red granite, and covered with a rich sward of sweet grass; there is very little heath: the marshes are few and not extensive, and are intersected by numerous drains. To the west of Jed Water, including Liddesdale, the dry soil either rests upon lime-stone or gravel. In this district are many mosses and much fenny land; likewise a large tract of strong clayey soil, lying on a cold tilth, or hard clay, which is impervious to water. In the arable division of the county the soil is partly light and partly heavy. The light consists of a rich loam, or mixture of loam and sand, of loam and gravel, of sand, or gravel and clay, in every various proportion. The heavy soil is chiefly clay of different depths and degrees of stiffness or mixtures, where clay prevails placed on tilth, or other matter retentive of water. In very few spots this surface lies on a dry bottom; and not unfrequently different and opposite soils are strangely blended in the same field. The light soil, however, is in general formed on low and level lands, near the beds of rivers, and their branches, and also on several eminences of considerable extent, especially in the parishes of Linton, Crailing, Ancrum, Maxton, and Melrose. The heavy soil rarely appears in the vallies, and chiefly occupies the higher grounds. The largest tract of it lies immediately south of Eildon Hills, including nearly the whole parishes of Minto, Lilliesleaf, and Bowden, a portion of Melrose, St. Boswell, Ancrum, Maxton, and Roxburgh parishes. It comprehends in all about 10,000 acres, of which at least one half is shallow, cold, and unkindly, difficult to labour and uncertain in its produce; on which many acres of it have been planted with trees. In the other half there is much rich and fertile land, which bears luxuriant crops both of corn and grass, and not a little of a middle nature between these extremes. In the parishes also north of the Tweed, the heavy soil is rather most prevalent, and is, in general, of a good quality. Another considerable portion of it runs along the higher grounds south of the Tweed, in the parishes of Springtoun, Kelfo, Roxburgh, and Exford, and there are detached fields of it in other parts of the district. In the bosom, or deeply indented

## ROXBURGHSHIRE.

dented into the sides of these clayey tracts, are pieces of dry land of an admirable quality for producing either white or green crops. Of the arable district at large, at least two-thirds may be designated light and dry.

*Agriculture.*—Farms in Roxburghshire are of every size, from 50 to 6000 acres; yielding from 50*l.* to nearly 3000*l.* annual rent. The arable farms include, in general, from 200 to 500 acres, but there are some far less and some much more extensive. One tenant frequently possesses two or three farms, and there are instances of the same persons leasing both an arable and a sheep farm, to obtain the double profit arising from rearing sheep to a larger size, by wintering them on after-grass and turnips, and fattening both them and their lambs earlier, and better, for the market. With the breeders of that valuable animal, turnips have been for many years a greater object than formerly, and hence some farmers have engaged more deeply in arable husbandry, instead of accumulating, as before, pasture farms. The character of farmers in this county, like the extent of the farms, admits of much variety: but it may be truly said, that the greater part of them are men of respectability and of agricultural enterprize. Rents are in every case paid in money. One or two clergymen, who have a right to tythes, have been accustomed from time immemorial to accept of a small sum in lieu of them. Leases differ in duration and conditions in the pasture and arable districts. In the former they extend only from seven to fifteen years; but in the latter they are given for nineteen or twenty-one years.

Considerable tracts of land here, particularly in the extensive district of Liddesdale, remain in a state of nature. The cold wet soil, already noticed, and the exposed situation, afford no encouragement for attempting agricultural improvements. This large tract is therefore wholly under sheep pasturage, except a few strips of land on the banks of the Hermitage and the Liddel. The most ancient agriculture in this county would appear to have been very different from the present. The marks of the plough, and of regular ridges, are still every where to be seen upon lofty mountains, where no grain can now be produced, and upon a soil which has ceased to be regarded as entitled to the appellation of arable land. These facts prove that the surface of the country must have formerly been in a very different state from that in which it now appears. The modern improvements in agriculture are all adopted here by the arable farmers. The first person who set the example of spirited exertion was William Dawson, esq. a farmer's son, who, after receiving a liberal education, was sent by his friends into England, for the purpose of obtaining a knowledge of the practical agriculture of that part of the united kingdom. He returned to his native country in 1753, and immediately introduced the practice of the turnip husbandry. At first his improvements were considered as rash and speculative, but his success soon effected a change of opinion. Mr. Dawson's neighbour perceiving the advantages of the new plan, became eager to understand and adopt it. The hinds which had once been in his service, were sure to find employment; his ploughmen were in the utmost request; they were transported to East Lothian and even to Angus, and every where diffused the improved practice of that valuable art. Roxburghshire became the scene of the most active agricultural enterprizes; and Mr. Dawson, independently of having acquired a large property, had the satisfaction to live to see himself regarded, and bear himself called, the father of agriculture in the south of Scotland.

The rotation of crops used in this county have nothing peculiar, or particularly requiring notice. On a dry soil, it is considered an object of importance to throw a large quan-

tity of land under turnip or grass, especially after lime. One part of Roxburghshire has long been celebrated for an early species of oats, denominated Blainfly oats, from the circumstance of their having been cultivated for time immemorial at Blainfly, a large district in the parish of Melrose, near the northern extremity of the county: the average produce there is six to one, but when they are grown on a rich dry soil, it is sometimes 16 or 18 to one. They are sold at an average of 3*s.* 6*d.* per boll dearer than common oats, and are only objectionable in one point of view, *viz.* that they are apt to shake out. Abundant crops of wheat are reared in the lower and more fertile districts of the county. Bar is likewise raised in considerable quantities; but the culture of peas and beans has become very limited, since the practice of turnip feeding has been so generally introduced. Of potatoes, comparatively few are cultivated; neither are great crops of hay frequent in this county, on account of the want of towns in which they might find a ready sale. Little flax is grown, except as an object of domestic manufacture. It is a remarkable fact, and a subject of curiosity in agricultural history, that this county was at one time likely to have become noted for the cultivation of tobacco. It was introduced by Mr. Thomas Mann, and was tried both at Newstead and at Kelfo with such success, that the legislature deemed it requisite to interfere, and put an end to its culture.

*Live Stock.*—Very considerable numbers of cattle are fed in Roxburghshire, but sheep is the staple animal of the county. The latter are estimated at nearly 300,000 in number, and are mostly of the Cheviot breed. A large quantity of ewe-milk cheese, of the best quality, has long been an object of manufacture here, but the practice is now on the decline. The horses employed and bred here are either of the English or of the Lanarkshire breed. Swine are reared by almost every cottager and farm-servant who is married; also vast quantities of poultry. Several cart-loads of the eggs of dunghill fowls are weekly collected by "egglers," who sell them in Berwick for the London market.

*Inclosures.*—A very small proportion of the lands in this county are inclosed. The fence chiefly used is ditch and hedge, of which there are two kinds, namely, the double and the single. The double consists of two ditches, having a hedge planted in the embankment between them. Where stones can be easily procured, stone-dike inclosures are preferred to the hedge and ditch. One of the most substantial fences of this kind in the county incloses about 600 acres, called the "Deer park of Holydean," on the Roxburgh estate. It is traditionally stated to have been constructed before the year 1500. It is about four feet high, and though built of whinstone only, without lime or mortar, continues to be a good fence. In a few places dikes are formed of alternate layers of stone and turf.

*Towns, Villages, and Fairs.*—There is only one royal borough in this county, that of Jedburgh, which, along with the boroughs of Haddington, Lauder, Dunbar, and North Berwick, elects a member to serve in parliament. This place is the county town, and makes a considerable figure in the history of the border wars. (See JEDBURGH.) The other principal towns and villages are, Hawick, which is situated at the confluence of the Teviot and Slittridge, near the lower part of the upper, or most mountainous district of the county; Kelfo, which stands on the northern bank of the Tweed; and Melrose, celebrated for its abbey, each of which the reader will find described under their respective names.

The greatest fair in the county is held in the parish of

Leffudden, or St. Boswell, whence it is called St. Boswell's fair. It takes place on the 18th of July, and is the principal mart for sheep and lambs in the south of Scotland; but horses, linen, and woollen cloths, are likewise sold in considerable quantities. The customs of this fair belong to the duke of Buccleugh, and may be estimated at about 50*l.* per annum. Another great fair is held in the vicinity of Kelso. It is called St. James's fair, from the circumstance of its being holden within the ancient parish of that name, which is now merged in the parish of Kelso.

*Antiquities.*—The vestiges of ancient times still visible in Roxburghshire are numerous. Mutilated encampments, and ruined buildings of strength, are discovered in a great variety of situations, and particularly in the high district of the county. In the parishes of Cavers, Hawick, and others, remnants may be traced of what is called the Cat-rail, which is conjectured to have been a boundary rampart, similar to the Wanfdike and Offa's dike in England; but whether erected by the Romans, Saxons, or Britons is uncertain; though Whitaker, in his History of Manchester, contends strongly that it is of British origin. In the parish of Robertson, near the source of the Teviot, is a large square encampment, which is still denominated *Africa*, and in the vicinity are several smaller semi-circular intrenchments. There are likewise encampments on the Eildon hills, on Carberry hill, Sidelhill, at Ancrum, and on the farm of Flight, in the parish of Clintwood. In the same parish are likewise numerous fortifications, called Picts' works, which are of a circular form, and constructed of large stones. On the farm of Millburn is a small circle of nine upright stones, surrounded by a ditch, which is supposed to have been a Druidical temple. Cairns appear in different parts of the county. Of these, the most remarkable is at Whiggills. The quantity of stones is immense, and they are mostly of a very large size. Near it is a large upright stone, called the "standing stone." This cairn is situated in the centre of an extensive and deep moss, where not a stone is to be discovered except those employed in its construction. Another immense cairn is placed on an eminence between the parishes of Castleton and Canonby. It is eighty-six yards long, and consists of masses of free-stone, of great magnitude. A standing stone, thirteen feet in circumference, and seven feet above ground, is fixed at the north end of it; and there are five other smaller ones, forming, with the larger stone, a circle round the cairn forty-five yards in diameter. How these enormous masses were originally collected, or for what purpose, it is very difficult to determine. At Milnholm, in the parish of Canonby, stands an ancient cross, formed of one stone, eight feet four inches high, on which are sculptured a sword and some ancient writing; but the latter is so much mutilated, that it cannot be read. On the banks of the Ale Water, near Ancrum, is a series of caves, some of which still preserve vestiges of fire-places, and holes for the passage of smoke. Similar caves are discovered on the banks of the Jed.

Roxburghshire formerly abounded with towers, or petty fortresses, erected by the border chieftains, for the defence of the country from the incursions of the English borderers. Few of these, however, now remain; indeed the only ones entire are Delphinstone tower, and another at Mofsburnford. Of the larger castles, the principal are Clintwood castle, Goldieland castle, Gossford castle, and Roxburgh castle, the last of which is mentioned under ROXBURGH. In this county are situated the ruins of three monasteries, among the most important in Scotland, *viz.* Melrose, Kelso, and Jedburgh abbies. See MELROSE, KELSO, and JEDBURGH.

*Eminent Natives.*—Roxburghshire boasts to have been the

birth-place of several characters distinguished in the annals of literature and military glory. Of these, the most noted were Thomson, author of the Seasons; Armstrong, author of the "Economy of Love," and various miscellaneous poems; Gavin Douglas, who translated several of the works of the Latin poets into Scottish verse; and general Elliot, afterwards lord Heathfield, the gallant defender of Gibraltar, when it was attacked in 1786, by the combined powers of France and Spain. Beauties of Scotland, vol. ii. 1805. Agricultural Survey of the Counties of Roxburgh and Selkirk, by Robert Douglas, D.D., 8vo. 1800.

ROXBURY, a pleasant town of America, in Norfolk county, Massachusetts; 1 mile S.W. of Boston. It is now divided into three parishes, and was settled in 1630. The three parishes contain 3669 inhabitants. The first of these parishes has been lately connected with Boston harbour by a canal. The famous John Eliot, called the apostle of the Indians, was the first minister who settled in this place. He translated the Bible, and other pious books, into the Indian language; and founded many religious societies among the Indians. Some few remain to this day. He died in 1670, after being pastor 60 years.—Also, a township in the W. part of Orange county, Vermont, containing 361 inhabitants.—Also, a township of Morris county, New Jersey, on Munconecunk river, 25 miles from its confluence with the Delaware, and 45 miles N. of Trenton; containing 1563 inhabitants. Near it is a mineral spring.—Also, a town in Litchfield county, Connecticut, containing 1217 inhabitants.—Also, a township of Washington county, in the state of Ohio, containing 408 inhabitants.

ROXCESTER. See WROXETER.

ROXEN, a lake of Sweden, in East Gothland; 100 miles W.S.W. of Stockholm.

ROXO, CAPE, a cape on the S.W. coast of Porto Rico. N. lat. 18° 1'. W. long. 65° 50'.—Also, a cape of Spain, on the coast of Valencia. N. lat. 37° 53'. W. long. 0° 50'.—Also, the S.E. point of a small island in the gulf of Mexico, situated before the mouth of the river Panuco. N. at. 22° 30'. W. long. 100° 11'.—Also, a cape on the W. coast of Africa. N. lat. 12° 15'. W. long. 16° 35'.

ROY, LOUIS LE, in *Biography*, a learned professor, born at Constance, in Normandy, about the beginning of the 16th century. After having studied in Italy and other places, he settled at Paris, where, in 1570, he was appointed to the professorship of Greek. After this he studied the law four years at Toulouse; he frequented the bar at the parliament of Paris, in which he exercised some kind of magistracy. He sometimes followed the armies; and had visited the courts of the emperor, and king of England. His inattention to domestic affairs reduced him at last to depend upon the liberality of others for his daily subsistence. He died at an advanced age in the year 1571, leaving behind him, as monuments of his learning, many works in the Latin and French languages. In the former he gained considerable reputation, by an elegantly written life of the learned Budæus. He gave good translations into the French of the works, or part of them, of Plato, Aristotle, and Demosthenes, which he enriched with learned commentaries.

ROY, JULIEN-DAVID LE, an architect and antiquary, born at Paris in 1728, was the son of Julien le Roy, a celebrated mechanist, who excelled particularly in the art of watch-making, so much so, that his time-pieces acquired the same celebrity in France as those of Graham in England; he died at Paris in 1759, at the age of 74, leaving four sons; of whom Julien, the subject of this article, was educated for the profession of an architect, in which he became eminent. He is well known in the literary world by the following

works;

works; "Ruines des plus beaux Monumens de la Grèce;" this obtained for the author admission into the Academy of Inscriptions; "Histoire de la Disposition et des Formes differentes des Temples des Chretiens;" "Observations sur les Edifices des anciens Peuples;" "De la Marine des anciens Peuples." He published two other works on the construction of the ships of the ancients; and a memoir on cutting masts in the Pyrenées. This ingenious man died at Paris in the year 1803, at the age of 75.

ROY, PETER, brother of the above, was watch-maker to the king, and published memoirs for the clock-makers of Paris,—Etreennes Chronometriques—Treatise on the Labours of Harrison and le Roy for the Discovery of Longitude at Sea. He died in 1785. It is well known, says a contemporary biographer, that the English, on account of their numerous discoveries in this art, had enjoyed such a reputation for the excellence of their clocks and watches, that they found every where a market, in preference to any others, and that the French themselves were obliged to come to England for their time-pieces. Julien le Roy, the father, had the honour of removing, in part, this pre-eminence, and of transferring it to the French. He made many discoveries in the construction of repeating-clocks and watches: in second and horizontal watches he invented an universal compass with a sight;—an extremely useful and simple contrivance for drawing a meridional line, and finding the declination of the needle; and also a new universal horizontal dial. It is to him we are indebted for the method of compensating for the effects of heat and cold in the balances of chronometers, by the unequal expansion of different metals, a discovery which has been brought by our English artists to a state of great perfection, although it had been thrown aside by the inventor's son, Peter.

ROY, in *Geography*, a town of Silesia, giving name to a lordship in the principality of Teschen; 6 miles N. of Teschen.

ROYA, EL, a town of Spain, in Old Castile; 10 miles N.N.W. of Soria.

ROYAL, *regal*, something relating to a king.

The word is French, formed from the Latin *regalis*, of *rex*, king.

In this sense we say, the royal family, the royal blood, royal line, &c.

In England, the prince and princess of Wales, the king's brothers, &c. are addressed under the title of *royal highness*.

ROYAL *Abbey*, denotes an abbey founded by a king, or by a prince who is succeeded by a king.

ROYAL *Academy of Arts*. See LONDON.

ROYAL *Academy of Sciences*, &c. See ACADEMY.

ROYAL *Academy of Music*. See OPERA.

ROYAL *Antler*, among *Hunters*, expresses the third branch of the horn of a hart or buck, that shoots out from the rear or main horn above the back-antler.

ROYAL *Army*. See ARMY.

ROYAL *Assent*, is that assent or approbation which the king gives to a thing done by others; as the election of a bishop by dean and chapter, or to a bill passed in both houses of parliament.

The royal assent in parliament being given, the bill is indorsed with these words, *Le roy le veut*; that is, *it pleases the king*. If he refuses it, thus, *Le roy s'avisera*, q. d. *the king will advise upon it*. See PARLIAMENT.

ROYAL *Boroughs*. See BOROUGH.

ROYAL *Crown*, is that worn by kings. See CROWN.

ROYAL *Charter*. See CHARTER.

ROYAL *African Company*. See COMPANY.

ROYAL *Exchange*, the bourse or meeting-place of the merchants in London.

It was first built in 1566, at the charge of sir Thomas Gresham; and in a solemn manner, by herald with found of trumpet, in presence of queen Elizabeth, proclaimed the Royal Exchange. Till that time the merchants met in Lombard-street.

It was built of brick, yet then esteemed the most splendid bourse in Europe. A hundred years after its building, at the great fire, it was burnt down; but it was soon raised again in a still more magnificent manner, the expence of it amounting to 50,000*l*.

One half of this sum was disbursed by the chamber of London, the other by the company of mercers; who, to reimburse themselves, let to hire a hundred and ninety shops above stairs, at twenty pounds each; which, with other shops, &c. on the ground, yielded a yearly rent of above four thousand pounds; yet the ground it stands on does not exceed three-fourths of an acre; whence it is observed to be much the richest spot of ground in the world.

It is a quadrangular building, with walks around, in which the merchants of the respective countries associate themselves. In the middle of the area, or court, is a fine marble statue of king Charles II., in the habit of a Roman Cæsar, erected by the society of merchant-adventurers; the workmanship of Grinlin Gibbons. Around are ranged the statues of the several kings since the Norman Conquest. See LONDON.

ROYAL *Fishes* are whales and sturgeon, and some add porpoises too; which the king, by his prerogative, is to have, whenever cast on shore, or wrecked, in all places of the realm; unless granted to subjects by express words.

ROYAL *Foot, Fort, Franchise, Hospital*. See the substantives.

ROYAL *Oak*, was a fair-spreading tree at Boscobel, in the parish of Donnington, in Staffordshire, the boughs of which were all covered with ivy; in the thick of which king Charles II. sat in the day-time with colonel Careless, and in the night lodged in Boscobel-house; so that they are mistaken who speak of it as an old hollow oak; it being then a gay flourishing tree, surrounded with many more. The poor remains of it are now fenced in with a handsome wall, with this inscription over the gate, in golden letters: FELICISSIMAM ARBOREM, QUAM IN ASYLUM POTENTISSIMI REGIS CAROLI II. DEUS OP. MAX. PER QUEM REGES REGNANT, HIC CRESCERE VOLUIT, &c. Phil. Trans. N<sup>o</sup> 310.

ROYAL *Oak, Rebur Carolinum*, in *Astronomy*, one of the new southern constellations, the stars of which, according to Sharp's Catalogue, annexed to the Britannicæ, are 12. See CONSTELLATION.

ROYAL *Officers*. See OFFICER.

ROYAL *Parapet*, or *Parapet of the Rampart*, in *Fortification*, is a bank about three fathoms broad, and six feet high, placed upon the brink of the rampart, towards the country; to cover those who defend the rampart.

ROYAL *Poop*. See POOR.

ROYAL *Port*. See PORT *Royal*.

ROYAL *Society of England*, is an academy, or body, of persons of eminent learning; instituted by king Charles II. for the promoting of natural knowledge.

This illustrious body had its original in an assembly of ingenious men, residing in London, who, being inquisitive into natural, and the new and experimental philosophy, agreed, about the year 1645, to meet weekly on a certain day, to discourse upon such subjects. These meetings, it is said, were suggested by Mr. Theodore Haak, a native of the Palatinate in Germany; and they were held sometimes at Dr. Goddard's lodgings in Wood-street, sometimes at a convenient place in Cheap-side, and sometimes in or near Gresham

Gresham College. This assembly seems to be that mentioned under the title of the "Invisible, or Philosophical College," by Mr. Boyle, in some letters written in 1646 and 1647. About the years 1648 and 1649, the company, which formed these meetings, began to be divided: those in London continued to meet there as before; and those who were removed to Oxford occasionally joined them. The latter, *viz.* Dr. Wilkins, Dr. Wallis, and Dr. Goddard, in connection with others, continuing their assemblies in Oxford, brought the study of natural and experimental philosophy into fashion there; meeting first in Dr. Petty's lodgings, afterwards at Dr. Wilkins's apartments in Wadham College, and, upon his removal, in the lodgings of the honourable Mr. Boyle. The greatest part of the Oxford society coming to London about the year 1659, they met once or twice a week in term-time, at Gresham College, till they were dispersed by the public distractions of that year, and the place of their meeting was made a quarter for soldiers. Upon the Restoration, in 1660, their meetings were revived, and attended with a larger concourse of persons, eminent for their character and learning.

They were at length taken notice of by the king, who was pleased to grant them an ample charter, dated the 22d of April 1663, by which they were erected into a corporation, "consisting of a president, council, and fellows, for promoting natural knowledge."

Their manner of electing fellows is by balloting. Their council are in number twenty-one, including the president, vice-president, treasurer, two secretaries, and secretary for foreign correspondence; eleven of which are continued for the next year, and ten more added to them; all chosen on St. Andrew's day. Each member, at his admission, subscribes an engagement, that he will endeavour to promote the good of the society; from which he may be freed at any time, by signifying to the president, that he desires to withdraw.

The charges are five guineas paid to the treasurer at admission; and thirteen shillings *per* quarter, so long as the person continues a member; or, in lieu of the annual subscription, a composition of twenty-six guineas in one payment.

Their design is, to "make faithful records of all the works of nature or art, which come within their reach; so that the present, as well as after-ages, may be enabled to put a mark on errors which have been strengthened by long prescription; to restore truths that have been neglected; to push those already known to more various uses; to make the way more passable to what remains unrevealed," &c.

To this purpose they have made a great number of experiments and observations on most of the works of nature; eclipses, comets, meteors, mines, plants, earthquakes, inundations, springs, damps, subterraneous fires, tides, currents, the magnet, &c. Also numbers of short histories of nature: arts, manufactures, useful engines, contrivances, &c. The services they have been of to the public are very great. They have improved naval, civil, and military architecture; advanced the security and perfection of navigation; improved agriculture; and put not only this kingdom, but also Ireland, the plantations, &c. upon planting.

They have registered experiments, histories, relations, observations, &c. and reduced them into one common stock; and have, from time to time, published some of the most immediate use, under the title of Philosophical Transactions, &c. and laid the rest up in public registers, to be nakedly transmitted to posterity, as a solid ground-work for future systems. See TRANSACTIONS.

They have a library adapted to their institution; towards which Mr. Henry Howard, afterwards duke of Norfolk, contributed the Norfolkian library, and which is, at this time, greatly increased by a continual series of benefactions. The museum, or repository, of natural and artificial rarities, given them by Daniel Colwal, esq., and since enriched by many others, is now removed to the British Museum, and makes a part of that great repository. Their motto is, NULLIUS IN VERBA; and their place of assembling is Somerset-place, in the Strand. Sir Godfrey Copley, bart., left five guineas to be given annually to the person who should write the best paper in the year, under the head of experimental philosophy. This reward, which is now changed to a gold medal, is the highest honour the society can bestow. It is conferred on St. Andrew's day.

ROYAL Society of Musicians. See MUSICAL FUND, and ROYAL SOCIETY of Musicians.

ROYAL Spanish Academy. See ACADEMY.

ROYAL Sugar. See SUGAR.

ROYAL, in *Sea Language*, is a name given to the highest sail which is extended in any ship. It is spread immediately above the top-gallant sail, to whose yard-arms the lower corners of it are attached. The sail is never used but in light and favourable breezes.

ROYAL Stay. See STAY.

ROYAL Yard. See YARD.

ROYALS, in *Artillery*, are a kind of small mortars, which carry a shell, whose diameter is five inches and a half. See MORTAR.

ROYAL Bay, in *Geography*, a bay on the N.E. of the island of Georgia, between Cape George and Cape Charlotte.—Also, a bay on the N. coast of Antigua, a little to the E. of Peyerfan's Point.

ROYAL, or *Minong, Island*, an island about 35 miles long, and 12 wide, in the N.W. part of lake Superior. N. lat. 47° 52'. W. long. 89°.—Also, a small fertile island in the river St. Lawrence, 60 miles below lake Ontario. N. lat. 44° 46'. W. long. 75° 24'.

ROYAL Reach, a channel in the straits of Magellan, extending from Fortescue bay to Passage Point.

ROYAL Sound, a large bay on the coast of Kerguelen's land, between Cape George and the Prince of Wales's Foreland.

ROYAL'S River, a river of America, in Cumberland county, Maine, which runs into Casco bay, in the township of North Yarmouth.

ROYALSTON, a township of Worcester county, Massachusetts; 40 miles N.W. by N. of Worcester; incorporated in 1665, and containing 1415 inhabitants. Miller's river traverses this town from the east.

ROYALTIES, REGALITIES, the rights of the king; otherwise called the *king's prerogative*, and the *regalia*. See PREROGATIVE and REGALIA.

Of these, some the king may grant to common persons; others are inseparable from the crown.

ROYALTON, in *Geography*, a township of Windsor county, in the state of Vermont, N.W. of Hartford, on White river, containing 1748 inhabitants.

ROYAMUNGAL, a river of Bengal, which runs into the bay of Bengal, N. lat. 21° 35'. E. long. 89° 18'.

ROYAN, a town of France, in the department of the Lower Charente, on the Garonne; fortified by the Huguenots, and defended so vigorously against Louis XIII. in the year 1621, that he was compelled to withdraw his troops; but he afterwards avenged his disgrace, by demolishing it so entirely, that the present place is only the suburbs of the former; 12 miles S. of Marennes.

ROYAUMEIZ,

ROYAUMEIX, a town of France, in the department of the Meurte; 6 miles N. of Toul.

ROYBON, a town of France, in the department of the Iſere, and chief place of a canton, in the diſtrict of St. Marcellin; 7 miles N.N.W. of St. Marcellin. The place contains 2412, and the canton 7373 inhabitants, on a territory of 190 kilometres, in 11 communes.

ROYE, a town of France, in the department of the Somme, and chief place of a canton, in the diſtrict of Montdidier; 15 miles S.S.W. of Peronne. The place contains 3176, and the canton 14,027 inhabitants, on a territory of 195 kilometres, in 39 communes. N. lat. 50° 8'. E. long. 2° 52'.

ROYENA, in *Botany*, named by Linnæus in honour of Adrian Van Royen, profeſſor of Botany in the univerſity of Leyden, who died in 1779, aged 74, and was ſucceeded by his nephew David, who died in 1799.—Linn. Gen. 221. Schreb. 299. Willd. Sp. Pl. v. 2. 631. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 61. Thunb. Prodr. 80. Juff. Gen. 156. Lamarek Dict. v. 6. 320. Illuſtr. t. 370. Gærtn. t. 94.—Clasſ and order, *Decandria Digynia*. Nat. Ord. *Bicornes*, Linn. *Guaiacane*, Juff.

Gen. Ch. Cal. Perianth inferior, of one leaf, urn-shaped, five-cleft, permanent. Cor. of one petal; tube the length of the calyx; limb ſpreading, revolute, deeply cleft into five, ovate ſegments. Stam. Filaments ten, very ſhort, ſpringing from the corolla; anthers oblong, acute, twin, erect, as long as the tube. Piſt. Germen ſuperior, ovate, terminating in two ſtyles, a little longer than the ſtamens; ſtigmas ſimple. Peric. Berry inveſted with the coriaceous calyx, fleſhy, of four cells, two of them often abortive. Seed. Nuts ſolitary, ovate, ſomewhat triangular.

Eſſ. Ch. Calyx urn-shaped. Corolla of one petal, with a revolute limb. Berry of four cells, two of them moſtly abortive.

1. *R. lucida*. Shining-leaved African Bladder-nut. Linn. Sp. Pl. 568. (*Staphylodendron africanum ſempervirens, foliis ſplendentibus*; Commel. Hort. v. 1. 187. t. 96.)—Leaves ovate, roughiſh with hairs.—Native of the Cape of Good Hope, as indeed are all the remaining ſpecies. It flowers in May and June.—The ſtem of this evergreen ſhrub is eight or ten feet high, branched in all directions. Leaves generally alternate, on ſhort ſtalks, ovate, pointed. Flowers axillary, along the branches, very inconſpicuous. Berry red, and ſheſhy like an apple.

2. *R. villoſa*. Heart-leaved Royena. Willd. n. 2.—Leaves heart-shaped, oblong, downy beneath.—It flowers in June and July.—Very ſimilar to the laſt in habit, but its branches are more villous. Leaves elliptic or oblong; heart-shaped at the baſe; on ſhort, hairy ſtalks. Flowers axillary, nodding, ſolitary, on villous ſtalks. Bracts two, oppoſite, ovate, pointed, downy, large, deciduous.

3. *R. pallens*. Pale Royena. Willd. n. 3.—“Leaves longiſh-obovate, obtuſe, ſmooth.”—It flowers in June and July.—We know not of any deſcription or figure of this ſpecies which ſtands on the authority of Thunberg, Aiton, and Willdenow, who merely give its ſpecific character.

4. *R. glabra*. Myrtle-leaved African Bladder-nut. Linn. Sp. Pl. 568. (*Vitis idæa æthiopicæ, buxi minoris folio, floribus albis*; Commel. Hort. v. 1. 125. t. 65.)—Leaves lanceolate, ſmooth.—Flowers in September.—Stem ſhrubby, five or ſix feet high, ſending out numerous ſlender, leafy, evergreen branches, covered with a purpliſh bark. Leaves rather ſmall, ovate, pointed, entire, bright green. Flowers axillary, along the branches, white. Berry roundiſh, purple, ripening in our greenhouſes in the winter.

5. *R. hirsuta*. Hairy-leaved African Bladder-nut. Linn.

Sp. Pl. 568. “Jacq. Collect. ſuppl. 110. t. 13. f. 1. fragm. t. 1. f. 2.”—Leaves oblong-lanceolate, rather villous.—Flowers in July.—Stem ſtrong and woody, ſeven or eight feet high, alternately branched, with a grey bark. Leaves an inch long, covered with ſoft hairs. Flowers on ſhort ſtalks, axillary, ſmall, of a faded purple colour.

6. *R. polyandra*. Oval-leaved Royena. Linn. Suppl. 240. Willd. n. 6.—Leaves elliptical. Flowers polyandrous, polygamous.—Time of flowering unknown.—The ſtem has knotty, irregular branches. Leaves ſomewhat obovate, coriaceous, finely downy on both ſides. Flowers in ſhort, axillary, downy cluſters.

7. *R. anguſtifolia*. Willow-leaved Royena. Willd. n. 7.—Leaves lanceolate, acute, ſomewhat hairy beneath. It flowers in June and July.—This ſpecies is adopted on the authority of Willdenow, who obſerves, that it differs from all the foregoing ones, in having narrow, lanceolate leaves, ſharp at both ends, and ſomewhat hairy underneath.

ROYENA is very nearly allied to *Diospyros*; the chief points of difference conſiſting in the latter genus having from ſix to twelve cells in the fruit, and ſometimes five or ſix diviſions in the calyx. Linnæus’s deſcription of the fruit of *Royena* is erroneous. See *Diospyros*.

ROYENA, in *Gardening*, contains plants of the ſhrubby evergreen exotic kind for the greenhouſe, of which the ſpecies cultivated are; the ſhining-leaved royena, or African bladder-nut (*R. lucida*); the heart-leaved royena, or African bladder-nut (*R. villoſa*); the myrtle-leaved royena, or African bladder-nut (*R. glabra*); the hairy-leaved royena, or African bladder-nut (*R. hirsuta*).

*Method of Culture*.—Theſe plants are often rather troubleſome in railing, but their culture may be attempted by cuttings and layers. The cuttings ſhould be made from the young ſhoots, and be planted in the early ſpring in ſmall pots filled with a loamy earth, plunging them in a very moderate hot-bed, covering them carefully with hand-glaſſes, reſreſhing them often with water in ſmall proportions. When they have ſtricken roots, and are begun to ſhoot, inure them gradually to the open air, and when they are well rooted remove them into ſeparate ſmall pots, managing them afterwards as other rather tender greenhouſe plants, ſuch as the orange-tree, &c.

And the layers may be made from the young bottom ſhoots, laying them carefully down by ſlitting them as for carnations, watering them often in the warm ſeaſon, but very moderately in the cold. When they are become well rooted, take them off and plant them in ſeparate pots in the ſame manner as the cuttings, giving them the ſame ſort of management afterwards.

The laſt ſort often ſends up ſuckers from the roots, and may ſometimes be increaſed by planting in the ſame way as the cuttings. They afford variety among other greenhouſe plants.

ROYERRE, in *Geography*, a town of France, in the department of the Creuſe, and chief place of a canton, in the diſtrict of Bourgaſneuf; 9 miles S.E. of Bourgaſneuf. The place contains 1476, and the canton 6675 inhabitants, on a territory of 290 kilometres, in 11 communes.

ROYMATLA, a river of Hindooſtan, which is one of the mouths of the Ganges.

ROYMUNGUL, one of the mouths of the Ganges.

ROYOC, in *Botany*. See *ROIOC*.

ROYON, in *Geography*, a town of France, in the department of the ſtraits of Calais; 10 miles N.W. of St. Pol.

ROYPOUR, a town of Hindooſtan, in Oude; 25 miles N.W. of Manickpour.—Allo, a town of Bengal; 30 miles

miles N.N.W. of Midnapour.—Also, a town of Hindooftan, in the circar of Boggilcund; 20 miles E. of Rewah.

**ROYSTON**, a town situated partly in Cambridgeshire, and partly within that of Hertford, is seated at the bottom of a hill, among the chalk downs. The name appears to have been derived from a cross, erected in the beginning of the twelfth century by a lady Roife, or Roisia, and thence called "Roife's Cross;" near to which a monastery for Austin canons was afterwards built: the canons being competently endowed, houses and inns were erected, and in time formed a town, called Roife's Town, which was afterwards contracted to Roylton. At the time of the Domesday Survey, the town was situated in five parishes, and so continued till the 32d year of king Henry VIII., when it was constituted a distinct parish: and the church of the dissolved priory being made parochial, was, agreeably to the letter of the statute, denominated "The Parish Church of St. John Baptist in Roylton." The estates granted to the priory by the founders appear to have included nearly all the land on which the town now stands. In the first year of Richard I. the canons obtained the liberty of holding a weekly market, and also an annual fair during the whole of Whitsun week. Henry III. invested them with many additional privileges: and under these grants the trade and population of the town rapidly increased. The greater part of the houses were destroyed by fire in the reign of Henry IV.; but the convenient situation of the place as a corn-market contributed to its speedy restoration: and in the time of Henry VI., according to Hollinshed, wheat was so plentiful here as to be sold for twelve-pence the quarter. Camden mentions this town as being famous for the great resort of maltsters and other dealers in grain; and for the incredible quantity of corn to be seen every market day on the adjacent roads. It is still celebrated for its corn trade, notwithstanding the great alteration which has taken place in the modes of traffic. The site of the priory with its appurtenances and liberties, and three annual fairs, were granted by Henry VIII., in consideration of 176*l.* 5*s.* 0*d.* to Robert Chester, esq. whose posterity continued to possess the same for several generations: but these are now the property of the honourable Thomas Brand. Only a few remains of the priory buildings are now left, excepting the church, which consists of a nave, chancel, and aisles, with a low tower. Besides the priory, there were two other religious foundations in this town. One of them, an hospital dedicated to St. Nicholas, was founded so early as king John's reign; but no particulars of it are now known. The other, which was also an hospital or free chapel, was dedicated to St. John and St. James, and was in existence in the twelfth year of Henry III., as Walter de Gray, archbishop of York, then granted indulgences to such as should contribute to the support of its sick and weak brethren. Some remains of this hospital are yet extant in a dwelling-house. King James I. built a mansion here, as an occasional residence for enjoying the amusements of hawking and hunting. At the commencement of the civil wars Charles I. removed from Hampton-Court to this house. It is still called the king's house, but is fallen to decay. Beneath the market-place is a *Cave*, or subterraneous crypt or oratory, which has been dug out of the solid chalk, and had originally a perpendicular aperture rising to the street, and communicating with the upper part of the cavity. This was of a circular form, about two feet in diameter, and had been closed by a mill-stone, which was accidentally discovered in August 1742. This aperture, or descent, had holes for the feet cut into the chalk on each side; but as the lower part of

the crypt was found to be filled with loose earth and rubbish, this passage was quickly enlarged, the curiosity of the town's-people being strongly excited by the hope of discovering some concealed treasure. About two hundred loads of earth were drawn out; but the zeal of the labourers was only repaid by finding a skull, and other human bones, greatly decayed. The interior of this singular subterraneous apartment is completely circular, finished in a kind of dome above, broken only by the original entrance. Round the lower part of the sides is a series of rude carving of the crucifixion, several faints, and various other subjects from sacred and profane history. The bottom of this cell is surrounded by a raised seat about one foot high, and between two and three wide, but divided on the east side by a hollow place, called the Grave. The present entrance is by a regular descent or passage, nearly one hundred yards in length, formed in the chalk from an adjacent house. The diameter of the crypt is about twenty-five feet; and the height is between thirty and forty. The Roman road, called Ichfield Way, passed by this town. According to the population returns of the year 1811, the number of houses in this parish was 284, containing 1309 inhabitants. The market is held on Thursdays; and here are five annual fairs. Roylton is situated 20 miles N.E. from Hertford, and 37 miles N. from London. Beauties of England and Wales, vol. vii. by E. W. Brayley and J. Britton. Lyfons's *Magna Britannia*, Cambridgeshire. Stukeley's *Palæographia Britannica*.

**ROYTON**, a chapelry or township in the parish of Prestwich-cum-Oldham, and county of Lancaster, England, is two miles N. of the town of Oldham. This place abounds with cotton manufactories, which appear to have been settled here in consequence of the abundance of coal obtained. According to the population report of 1811, this township contained 625 houses, and 3910 inhabitants. Royton-hall is the seat of Joseph Pickford, esq. but formerly belonged to the Byron family, who possessed considerable landed property in the neighbourhood. The house is seated in a deep valley, surrounded by high hills. Beauties of England, &c. vol. ix. by J. Britton.

**ROZANNA**, a town of Lithuania, in the palatinate of Novogrodek; 48 miles S.W. of Novogrodek.

**ROZANS**, a town of France, in the department of the Higher Alps, and chief place of a canton, in the district of Gap; 10 miles W. of Serres. The place contains 900, and the canton 5024 inhabitants, on a territory of 195 kilometres, in 11 communes.

**ROZAS, LAS**, a town of Spain, in New Castile; 10 miles N.W. of Madrid.

**ROZE, NICOLAS**, in *Biography*, music-master of the church of the Holy Innocents at Paris, was born at Bourgneuf, in the diocese of Chalons-sur-Saône, in 1745. At seven years old he was received as a chorister in the collegiate church of Beaune, in Burgundy. Soon after, he had instructions from the abbé Roulleau of Dijon, music-master of Tournay. He had the misfortune to lose this amiable master in two years time, who had taught him to sing several motets or anthems in that short period. He was afterwards a considerable time totally without instructions. And what was still worse, he was under the authority of persons who prevented him from attempting composition.

The abbé Hornet, nephew to the maitre de chapelle of Notre-Dame, gave him lessons in singing, but he was absolutely forbidden composition by this master, for fear his application should injure the fine voice which nature had given him. At twelve years old he again found himself without an instructor, and going to the college of Beaune

to finish his classical studies, and afterwards to the seminary of Autun, where, during two years' residence, he composed the chief part of the chants which at present are adopted almost throughout the diocese.

At twenty-two years old he went into orders at Beaune. In 1669, as soon as he was admitted into priest's orders, he composed a mass, which he carried to Paris and presented to M. d'Auvergne, master of the king's band. This able professor encouraged him to pursue composition, and made him compose under his own eye a motet for the Concert Spirituel.

It was at this period that the abbé Roze began to make himself known; and this motet procured him the place of maitre de chapelle of the cathedral of Angers, which he retained five years.

In 1775 he was appointed to the Holy Innocents, and from that time he has continued to furnish the Concert Spirituel with motets; and though his style is modern, he has never deviated from the grandeur and solemnity besetting sacred music.

The abbé Roze is one of the best singing masters, in point of taste, at Paris.

He has published a system of harmony, or accompaniment, in which he modestly pretends to no more than to assist the students in harmony with methodical elementary principles, so clear, that children of eight years old shall find no difficulty in them. It often happens that able composers are unable to teach children the first elements of music for want of a well digested method. This the abbé Roze's system will be found, with respect to accompaniment. He has traced the chords from the fundamental base or key-note, through all the combinations of harmony allowable by ancient rules in one key. Laborde, 1788.

ROZESTVEN, in *Geography*, a town of Russia; 32 miles S. of Petersburg. N. lat. 52° 20'. E. long. 29° 50'.

ROZESTVENSKOI, a town of Russia, in the government of Tobolsk; 16 miles S.E. of Kemskoï.—Also, a town of Russia, in the government of Archangel, on the Pinega; 4 miles S.E. of Pineg.

ROZETT, CAPE, a cape on the western coast of France. N. lat. 49° 28'. W. long. 2°.

ROZIER, FRANCIS, in *Biography*, an eminent writer in economics, was born at Lyons in 1734. His father, who was engaged in commerce, dying while he was young, and without property, he entered into the ecclesiastical order, though his taste led him to agricultural and botanical pursuits. He obtained the place of director of the school of Lyons. In this situation he joined La Tourette in publishing, in 1766, "Elementary Demonstrations of Botany," a work that passed through many editions. In 1771 we find him at Paris, where he began to publish the "Journal de Physique et d'Histoire Naturelle," which was conducted a considerable time with great reputation. In this work he gave clear and interesting accounts of all new discoveries in physics, chemistry, and natural history. Through the recommendation of the king of Poland, he was presented to a valuable priory, when, being completely at his ease, he turned his attention to his favourite project of drawing up a complete body of rural economy. He now purchased a domain at Beziers, in the finest part of France, and engaged actively in country labours, and at the same time employed himself in the abridgment of the great works from which his compilation was to be formed. This was at length finished, under the title of "Cours d'Agriculture," in 10 vols. 4to., of which the last did not appear till after the author's death. In 1788 he went to Lyons, and was admitted a member of the academy, while the

government gave him the direction of the nursery ground of the Generality. On the unfortunate revolution, Rozier was one of its earliest partizans, but without ever entering into its excesses. He was, however, one of its victims; in September 1793, during the siege of Lyons, a bomb falling upon his bed, buried his body in the ruins of his house. He was author, likewise, of several treatises on the method of making wines, and distilling brandy, on the culture of turnip and cole-seed, on oil-mills, and other machinery.

ROZIER, CAPE, in *Geography*, a cape on the coast of Canada, in the gulf of St. Lawrence; 9 miles W. of cape Gaspe.

ROZIERES. See ROSIERES.

ROZOY, a town of France, in the department of the Seine and Marne, and chief place of a canton, in the district of Coulommiers. The place contains 1507, and the canton 13,199 inhabitants, on a territory of 312½ kilometres, in 28 communes.

ROZOY en *Thierache*, a town of France, in the department of the Aisne; 21 miles N.E. of Laon.

ROZVALINA, TOTAGAI, a town of Russian Tartary, near lake Kargaldzin. N. lat. 52° 44'. E. long. 68° 54'.

RSESCHOW, a town of Austrian Poland, in Galicia; 70 miles W. of Lemberg.

RUA, LA, a town of Spain, in Galicia; 25 miles N.E. of Orense.

RUAD, ROUAD, or *Rou-Waddé*, an island of the Mediterranean, anciently celebrated under the name of Aradus or Arad. N. lat. 34° 42'. E. long. 35° 57'. See ARAD.

RUADOK, or RHUWAEDOG, a village of North Wales, in the county of Merioneth, where a battle was fought between the Welsh, under Llywarch Hen and the Saxons; 2 miles E. of Bala.

RUALGO, a town of Italy, in the Cadorin; 4 miles S. of Cadora.

RUANEL, a town of Ceylon; 38 miles S.S.W. of Candy.

RUARUS, MARTIN, in *Biography*, was born at Krempeu, in Holstein, about the year 1587, and being designed for a Lutheran minister, he was educated in the principles professed by the disciples of Luther. But at Altdorf he became a convert to the Socinian doctrine, as taught in a private manner by professor Soncerus. When he was reproached and threatened by his family for deserting the principles of his forefathers, he justified his conduct, and defended the cause of free inquiry in matters of religion. Of his sincerity no doubt could be entertained, as he submitted to the loss of his patrimony rather than make a sacrifice of what he considered to be truth. He travelled over the greater part of Europe, and acquired respect and esteem wherever he went, by his great learning and excellent moral character. He was offered situations of trust and honour in England and Silesia, but declined them all. At length he became principal of the college of Racow in Poland; after which, about the year 1635, he became pastor to the Socinian church at Dantzie. In the year 1646, Calixtus used all his endeavours to bring him back to his original principles, but without effect. He died at Dantzie in 1657, at the age of 70. He wrote notes on the catechism of the Socinian churches in Poland, which were added to the addition of that work printed in 1665. Two volumes of his letters, each containing one hundred, were published after his death at Amsterdam. They are said to be curious and interesting, not only as they throw light on the history of Socinianism, but as they furnish the reader with valuable literary anecdotes. Among the author's

correspondents were father Merfenne, Hugo Grotius, and De Bergius.

**RUATUN, or RATTAN**, in *Geography*, an island in the bay of Honduras, about 30 miles in length and 12 in breadth, furrounded with rocks and shoals; with a harbour capable of containing a large fleet of ships. The English, in the year 1742, formed a settlement here for the purpose of carrying on the logwood trade, but it was soon abandoned. N. lat. 16° 24'. W. long. 87° 10'.

**RUBASS**, a town of Hindooftan, in the subah of Agra; 14 miles W. of Fattipour.

**RUBBER**, a large coarse file.

**RUBBER of Pencil Strokes**. See **CAOUTCHOUC**.

**RUBBER, in Electricity**. See **ELECTRICAL Machine**.

**RUBBERS**, among *Shepherds*, a disease in sheep. See **SCAB**.

**RUBBING-POST**, a post set up for the purpose of cattle, hogs, or other animals, rubbing themselves upon. Mr. Marshall, in his "Rural Economy of Norfolk," says, it is an excellent custom of the Norfolk farmer to erect rubbing-posts in the different parts of the inclosure he is feeding or teething; they keep the stock from the fences, and furnish them, no doubt, with an agreeable, and perhaps a salutary, amusement. Some he saw draw the crown of a tree, with the lower part of the boughs left on, into the middle of the close: this is less trouble than putting down a post, is easily rolled out of the way of the plough, and seems to be still more agreeable to the cattle. They are also useful in hog-sties.

These sorts of posts may probably be found of great service in the feeding pasture, for the purpose of the fattening stock rubbing themselves upon, as they tend to keep them easy and quiet, as well as to afford them that kind of agreeable feeling which may be of utility in promoting their progress towards a state of fatness.

**RUBBIO**, in *Commerce*, a measure for corn in Italy, containing 8 lappa, which are equal to  $7\frac{2}{3}$  English bushels.

**RUBBLE STONE**, *Grauwacke* of Werner, *Gres gris* of the French, is a particular kind of sand-stone, containing not only grains of quartz, siliceous schistus, or horn-stone, but also scraps of blueish argillite in a clayey cement, of which there is often no more than is barely sufficient to hold the grains together, sometimes with and sometimes without mica; commonly compact, sometimes slaty in the gross. Its colour is yellowish, or blueish-grey, or dark reddish-brown mixed with grey. Fracture, in the small, fine splintery, or earthy; hardness from 7 to 9, rarely 10. Sp. grav. from 2.64 to 2.685, but when withered only 2.60. See **Transition Rocks**.

**RUBECULA**, in *Ornithology*, a species of *Motacilla*; which see.

**RUBEFACIENT**, in *Medicine*, from *rubor*, *redness*, and *facio*, *I make*, or *produce*, a term which is used to denote those substances which, when applied externally, by friction or otherwise, excite the action of the superficial vessels, and, by filling them with red blood, occasion a suffusion of redness in the part.

The operation of a rubefacient is, therefore, analogous to that of a blister, but considerably less efficient as a remedy; since it produces, in fact, but a small degree of the incipient effect of a blister, *viz.* a very slight and superficial distension of the blood-vessels, scarcely amounting to inflammation. Rubefacients are employed under the same indications as blisters, and are intended, like them, to relieve some internal pain or inflammation, by exciting a counter-irritation, or, as some explain it, by revulsion; *i. e.* by drawing the fluids from the diseased to the external parts. The friction, by

means of which the rubefacient is usually applied, contributes also to the same effect.

The substances, by which this effect is produced, are of an acrid or stimulating nature, such as ammonia, turpentine, camphor, vinegar, the essential oils, spirits, &c.: and the diseases, which they are ordinarily used to relieve, are the slighter degrees of local internal inflammation. Thus, for the relief of a slight sore-throat, or inflammation of the tonsils, it is customary to rub the front of the neck with hot vinegar, or ammonia and oil; and the more external redness it produces, the more effectual is the internal relief. Slight pains in the chest are often materially alleviated by the use of a warm liniment or plaster, or by the use of the ointment of tartarized antimony, which excites not only redness, but pustules. And rheumatic affections of the joints are often more effectually removed by friction with a rubefacient, than by any other means. See **REVULSION**.

**RUBELLIO**, in *Ichthyology*, a name given by some authors to a small sea-fish of a red colour, caught in the Mediterranean, and more usually called by writers on these subjects the *erythrinus*.

**RUBELLITE**, in *Mineralogy*, is considered as a subspecies of tourmaline, of a reddish-violet colour. It differs from tourmaline, being infusible under the blowpipe, but it loses its colour and transparency. Its specific gravity is 3.1. It contains, according to Klaproth,

Silex	-	-	-	43.5
Alumine	-	-	-	42.25
Soda	-	-	-	9
Oxyd of iron and manganese	-	-	-	1.5

A specimen analysed by Vauquelin gave 7 parts in the 100 of oxyd of iron and manganese. This stone is sometimes used in jewellery. In the Greville collection of minerals in the British Museum, there is a magnificent specimen of the red rubellite, originally presented to Col. Symes by the king of Ava. It has been valued at 1000l.

**RUBELLUS**, in *Ichthyology*, a name given by some authors to the common roach, and by others to the rudd or finchale.

**RUBENACH**, in *Geography*, a town of France, in the department of the Rhine and Moselle, and chief place of a canton, in the district of Coblenz. The place contains 567, and the canton 6935 inhabitants, in 19 communes.

**RUBENS**, *Sir PETER PAUL*, in *Biography*. This most singularly accomplished man, and extraordinary painter, was the son of John Rubens and Mary Pipelings, both descendants of distinguished families of the city of Antwerp. His father was one of the principal magistrates of that place, when civil war desolated Flanders; and its calamities approaching the precincts of his abode, he left it for Cologne, in which city our artist was born in 1577. The day of his nativity was the feast of St. Peter and St. Paul, and from thence he received, at the baptismal font, the names of these apostles. From his infancy he discovered prompt and lively talents, which were cultivated by his parents with great care, in every branch of polite and classical literature; and he amply repaid their care by the high degree of success he attained.

The views of his parents were otherwise directed than to the arts, and Rubens was placed, when his education was completed, as a page to the countess of Lalain; a situation too humble, and attended with occupation too trivial, to engage or detain long, in its obsequious frivolities, such a mind as he possessed; and on the death of his father, which happened soon after, he obtained permission of his mother to pursue the bent of his inclination, and became a painter.

To forward this view, he placed himself as a disciple of Tobias Verhaecht, a landscape painter of some note, but soon left him, to study history painting under Adam Van Ornt. As the vulgar and brutal department of that art were little congenial to the elevated and gentle mind and disposition of Rubens, he soon quitted him also, and then entered the school of Otho Venius, who possessed qualities, both as a man and an artist, far more suited to his taste; and he became attached to this his last preceptor, in the warmest and most respectful degree.

When Rubens had attained his twenty-third year, Otho had the candour to tell him that he could no farther promote his progress; and advised him to travel to Italy, and gather the rich fruit of higher cultivation in art, at that rich storehouse and fertile nursery of taste and talent. This wife and parental advice of his master corresponded entirely with his own inclination, that he immediately prepared for the journey; and having received strong recommendatory letters from the archduke Albert, governor of the Netherlands, to Vincenzo Gonzaga, duke of Mantua, he set forth for Italy.

Devoting a short time to the examination of the fine works at Venice, he proceeded to Mantua, where he received most marked attention from the duke, who was no less pleased with his polite accomplishments, than with his skill as an artist, and soon after appointed him one of the gentlemen of his chamber. His residence with this prince afforded him every desirable means of seeing and studying the great works of Giulio Romano, in the palace del T, with which he is said to have been peculiarly delighted; and he had continued with him two years, when he requested permission to go to Venice, the empire of colouring, for the purpose of studying still farther the works of Titian and others, which had so much engaged his attention as he passed through that city. On his return to Mantua he evinced how much he had benefited by studying the rich and brilliant productions of the Venetian school, in the three magnificent pictures he painted for the church of the Jesuits; which, in bravura of execution, and freedom of force in effect, rank nearly among his best productions. His patron afterwards gave him a commission, which afforded him the means of pursuing his studies at Rome, where he had not yet been, which was to make copies for him of some of the most celebrated pictures there, and he received it with gratitude and delight. During his residence there he executed several of these transcripts with uncommon success, and they were esteemed by the duke almost equal in value with the originals.

In 1605, Rubens was honoured by his friend with another commission, which still further assisted to advance his knowledge of the art, whilst it served the views of the prince. He was sent on an embassy from Mantua to the court of Spain, and went to Madrid, carrying with him magnificent presents for the duke of Lerma, the favourite of Philip III. He executed his mission with the success which attends ability and integrity; and while intent upon the political part of his employment, did not neglect to employ his pictorial talents with full power, gaining the esteem and admiration of the king of Spain, whose portrait he painted, and from whom he received the most flattering marks of approbation.

Soon after his return to Mantua, he revisited Rome, where he was engaged to adorn the tribune of Sta. Maria, in Valticella; there he painted three admirable pictures, in which he appears to have imitated the style of P. Veronese. From Rome he went to Genoa, where the reputation he had acquired greatly excited public curiosity, and he was engaged to paint many pictures. Among them he executed

two for the church of the Jesuits, the subjects of which were, the Crucifixion, and St. Ignatius performing a miracle, which gave universal satisfaction and delight.

Having been absent from his native country eight years, he was summoned home by the reported illness of his mother; but though he hastened with all speed, he did not reach Antwerp in time to afford his beloved parent the consolations of his presence and affections. The loss of her affected him deeply, and he intended, when he had arranged his private affairs, to go and reside in Italy; but the archduke Albert, and the Infanta Isabella, exerted their interest to retain him in Flanders, and in their service. He consequently established himself at Antwerp, where he married his first wife, Elizabeth Brants, and built a magnificent house, with a saloon in form of a rotunda, which he enriched with antique statues, busts, vases, and pictures by the most celebrated painters: and here, surrounded by works of art, he carried into execution those numberless productions of his prolific and rich invention, which once adorned his native country, but now are become the spoil of war, and the tokens of conquest and ambition, shining with equal lustre among other super-eminent productions of painting in the gallery of the Louvre.

The amazing success of Rubens in his art, and the honours and wealth which were accumulated upon him, excited the envy and malignity of many among his rivals, who ascribed the most meritorious parts of his works to the ability of his pupils, among whom were Jordaens, Van Uden, Snyders, Wilden, &c. and forgetting that such men would not consent to work for another whom they did not regard as pre-eminent to themselves. Cornelius Schut abused him for lack of invention. Abraham Jansens had the audacity to defy him to a trial of strength. Rubens answered, that he would contend with him when he had shewn himself to be a worthy competitor. A more friendly offer was rejected by him with equal wit. A chemist offered him a share of his laboratory, and of his hopes of obtaining the philosopher's stone. He carried the visionary into his painting room, and told him his offer came twenty years too late, for so long, said he, is it since I found the art of making gold with my palette and pencils. The abuse of Schut and of Rombouts, who joined in it, he answered by relieving their necessities, and procuring them employment; and by engaging in those varieties of art, landscapes, lion and crocodile-hunting, and other miscellaneous subjects, he decidedly established his claim to the title of an universal painter, and covered his calumniators with shame and confusion.

In 1620, when his talents had procured him universal renown, he received a commission from Mary de Medici to adorn the gallery of the palace of the Luxembourg. There, in consequence, he executed the works so well known; in which he represented, with the most rich and varied imagination, by very ingenious allegorical and emblematical designs, the principal events in the life of that princess. The whole were executed at Antwerp, except two pictures, which he painted at Paris in 1623, when he went there to arrange the whole in the gallery: and thus, in the short space of three years, amidst innumerable other engagements, was this large series of compositions, extensive in their design, and rich in number of figures and in variety of colouring, completed: exhibiting an astonishing proof of the vivacity of his imagination, and the skill and dexterity with which he controlled the materials of his art. It was at this period that he became known to the duke of Buckingham, as that nobleman passed with his master, prince Charles, through France on his way to Madrid. He afterwards became the purchaser of Rubens's

rich museum of works of art, for which he is said to have given 10,000*l.* sterling.

On the return of Rubens to Antwerp, he was honoured with several conferences with the Infanta Isabella, and was by her dispatched on a political mission to the court of Madrid, where he arrived in 1628, and was most graciously received by Philip IV. He acquitted himself in his novel capacity to the satisfaction of that monarch, and his minister, the duke de Olivares, by both of whom he was highly esteemed; and while his talents as a diplomatist met with the success they merited, those of the painter were not neglected.

The duke de Olivares had just completed the foundation of a convent of Carmelites at the small town of Loeches, near Madrid, and the king, as a mark of his favour to the minister, commissioned Rubens to paint four pictures for their church, which he executed in his grandest style, and the richest glow of his colouring. The first is an allegorical design of the triumph of the new Law, which he has personified by a figure of Religion, seated on a superb triumphal car, drawn by four angels, with others bearing the crosses, with characteristic symbols; four figures, expressive of Infidelity or Ignorance, over which Religion is supposed to triumph, follow the car like slaves or captives bound in chains. The group is crowned with beautiful cherubims, that hover in the air with chaplets in their hands, disposed with singular art and the most charming effect. The companion picture represents the interview of Abraham and Melchisedech, who offers him bread and the tenth of his spoils. The other two pictures, of equal excellence with the above, represent the four doctors of the church, and the four evangelists, with their distinctive emblems: they are all of very large dimensions, and in composition and expression are not excelled by any of his works. He also painted eight grand pictures for the great saloon of the palace at Madrid, which are regarded among the most brilliant of his productions. Their subjects were the Rape of the Sabines; the battle between the Romans and Sabines; the Bath of Diana, Perseus, and Andromeda; the Rape of Helen; the Judgment of Paris, Juno, Minerva, and Venus; and the Triumph of Bacchus. He also painted a large portrait of the king on horseback, with other figures; and a picture of the martyrdom of the apostle St. Andrew, which was in the church dedicated to that saint. For these extraordinary productions he was richly rewarded, received the honour of knighthood, and was presented with the golden key as gentleman of the chamber to the king. In 1629 he returned to Flanders, and thus, in the short space of little more than nine months, he designed and executed so extensive a series of pictures; a labour which, to any other artist not possessed of his extraordinary powers, must have required the exertion of many years. When he had rendered the account of his mission to the Infanta, she dispatched him to England, to sound the disposition of the government on the subject of a peace. There for a time he concealed the powers granted to him to negotiate upon the subject. Charles, in the interim, honoured this great painter with his notice, and commissioned him to paint the ceiling of the banqueting-house at Whitehall, where he has represented the apotheosis of king James I.

During one of the frequent visits with which Charles honoured Rubens, whilst he was engaged in this great work, the latter, with infinite address, took a favourable opportunity of touching on the subject of peace with Spain; and finding that the monarch was no ways averse to it, at length produced the credentials with which he was furnished. The king appointed some members of the council to negotiate with him; and the business was speedily

brought to a conclusion. Charles, delighted both with the man and the artist, munificently rewarded Rubens, and on the 21st of February 1630, conferred upon him the honour of knighthood. Soon afterwards, the important object of his mission being happily effected, he returned to the Netherlands, where he was received with all the honours and distinctions due to exalted merit.

Rubens continued to enjoy his well-earned fame and honours, with uninterrupted success, till he arrived at his 58th year, when he was attacked with strong fits of gout, which debilitated his frame, and unfitted him for great exertions: he abandoned, therefore, all larger works, and confined himself to easel painting. Yet he continued to exercise his art until the year 1640, when he died, at the age of 63. He was buried, with extraordinary pomp, in the church of St. James at Antwerp, under the altar of his private chapel, which he had previously decorated with a very fine picture. A monument was erected to him by his wife and children, with an epitaph in Latin, eulogizing his talents and virtues, and displaying their success.

The victorious yet barbarous irruption of the French republicans into the Netherlands, robbed Flanders generally, and no place more than Antwerp, of the fine historical works of Rubens, of which at this period the gallery of the Louvre exhibits a most astonishing display; no less than fifty-two of his pictures, and among them several of the highest quality, being now exposed to view there. It is difficult to say which branch of the art most successfully employed his talents, in history, portraiture, animals, landscape, or still life: in all, his brilliancy of imagination, and wonderful skill in execution, are equally apparent. From his birth he had evinced a lively and uncommon portion of genius, which met the advantages furnished to him in his progress through life, with an ardour and success of which history scarcely affords a parallel. Both the number and merit of the works of Rubens are calculated to excite extraordinary attention. His fame is extended over a large part of the continent, and it may be truly said, that he has enriched his country, not only by the magnificent examples of art which he left, but also by what some may deem a more solid advantage, the wealth which continued till lately to be drawn into it, by the concurrence of strangers from all parts of the world to view them.

Rubens is not one of those regular and timid composers, who escape censure and deserve no praise. He produced no faultless monsters; his works abound with defects as well as beauties, and are liable, by their daring eccentricities, to provoke much criticism. But they have, nevertheless, that peculiar property, always the companion of true genius, that which seizes on the spectator, commands attention, and enforces admiration, in spite of all their faults. His productions seem to have flowed from his pencil with more than freedom—with prodigality: his mind appears to have been inexhaustible; his hand never wearied: the exuberant fertility of his imagination was, therefore, always accompanied by a correspondent spirit in the execution of his work.

“Led by some rule, which guides but not constrains,  
He finished more through happiness than pains.”

No man ever more completely laid the reins on the neck of his inclinations, no man ever more fearlessly abandoned himself to his own sensations, and depending on them, dared to attempt extraordinary things, than Rubens. To this, in a great measure, must be attributed that perfect originality of manner, by which the limits of the art may be said to have been extended. Endowed with a full comprehension

prehesion of his own character, he waited not a moment for the acquisition of what he perhaps deemed incompatible excellence: his theory once formed, he seldom looked abroad for assistance; there is consequently in his works very little that appears to be taken from other masters, and if he has occasionally stolen any thing, he has so well digested and adapted it to the rest of his composition, that the theft is not discoverable. But though it must be allowed that he possessed, in many respects, the true art of imitation, though he looked at nature with a painter's eye, and saw at once the characteristic feature by which every object is distinguished, and rendered it on canvas with a vivacity of touch truly astonishing; though his powers of grouping and combining his objects into a whole, and forming his masses of light and shadow and colour have never been equalled; and though the general animation and energy of his attitudes, and the flowing liberty of his outline, all contribute to arrest the attention, and inspire a portion of that enthusiasm by which the painter was absorbed and carried away; yet the spectator will at last awake from his trance, his eyes will cease to be dazzled, and then he will not fail to lament, that such extraordinary powers were so often misapplied, that not entirely cast away: he will enquire, why Rubens was content to waste so many requisites to the perfection of the art? why he paid no greater attention to elegance and correctness of form, to grace, to beauty, dignity, and propriety of character? Why every subject, of whatever class, is equally adorned with the gay colours of spring, and every figure in his compositions indiscriminately *fed on roses*. Nor will he be satisfied with the ingenious, but surely unfounded apology, that these faults harmonize with his style, and were necessary to its complete uniformity, that his taste in design appears to correspond better with his colouring and composition, than if he had adopted a more correct and refined style of drawing; and that perhaps, in painting, as in personal attractions, there is a certain agreement and correspondence of parts in the whole together, which is often more captivating than more regular beauty.

The redemption of what he wanted, is found in the universality of his power as an executive painter. In the smallest sketch, the lightness and transparency of his touch and colour, are no less remarkable than the sweeping rapidity and force of his brush in his largest works: and in all kinds of subjects, he equally keeps up his wonted superiority. His animals, particularly his lions and horses, are so admirable, that it may be said they were never properly, at least poetically, painted, but by him; his portraits rank with the best works of those painters who have made that branch of art their sole study; and his landscapes remind us of the lustre of Claude Lorraine and the grandeur of Titian. In the latter class of his works, the picturesque forms of his rocks and trees, the deep tones in his shady glades and glooms, the watery sunshine, the dewy verdure, the airiness and facility of his touch, exhibit a charm, and shew a variety of invention, which fascinate the observer, and leave him no inclination to dwell on the defects, though they are often neither few nor small.

As a colourist, Rubens, in comparison with Titian, the great master of the Venetian school, will rise or fall, according to the taste of the amateur. If he is less chaste than the Venetian, he is more brilliant; and if not by the truth of his colours, yet he claims our applause by the lustre and splendour of his tints. The latter, in his execution, mingled his hues as they are found in nature, in such a manner as to make it impossible to say where they begin or terminate; Rubens, on the other hand, laid his colours in their

places, one by the side of the other, and then very slightly mixed them by a touch of a soft pencil; not unfrequently leaving his prepared ground visible through parts of the colours, to produce an harmonizing tone. Of these different styles, the only correct mode of judging is by reference to the specific object of art, *the imitation of nature*, and then Titian's will be regarded as the most correct, though Rubens may be more alluring.

RUBENS, ALBERT, son of Peter Paul, was born at Antwerp in 1614, and succeeded his father in his post as secretary to the council, devoting his leisure to literary pursuits. He died in 1677, leaving behind him many works, as monuments of his great learning and sound judgment, of which the following may be mentioned. "Regum et Imperatorum Romanorum Numismata," which is a commentary on the medals of the duke of Arschot: "De Re Vestitaria Veterum:" "Dissertatio de Gemma Tiberiana et Augultea—de Urbibus Neocoris—de natali Die Cæsaris Augulli," which were published by Grævius in the *Theaurus Antiq. Roman.*

RUBENTIA, in *Botany*, so called by Commerfon, from the vernacular name of the tree in the Mauritius, *Bois Rouge*; see ELEODENDRUM. See also RHAMNUS *pentaphyllus*, where we ought to have observed that the plant of Desfontaines and Boccone is very different from *Elaeodendrum Argan*, to which the synonyms of Linnæus and Jacquin most probably belong, as cited in our vol. 12th.

RUBEOLA, the diminutive of *Rubia*; Tourn. *Inst.* 130. t. 50. See ASPERULA and CRUCIANELLA.

RUBETA, or TOAD, in *Zoology*, a species of *Rana*; which see.

RUBETRA, in *Ornithology*, a species of *Motacilla*; which see. It is also a name by which Gesner and some others have called that species of the ænanthe, commonly known by the names of the *stone-chatter*, *stone-snick*, or *moortitling*. (See MOTACILLA *Rubicola*.) Other species of *Motacilla* are also called by the same name. See also MUSCICAPA and PIPRA.

RUBIA, in *Botany*, derived from *ruber*, red, on account of the fine scarlet colour afforded by its root; which is well known to dyers and tanners under the name of Madder.—*Linn. Gen.* 52. *Schreb.* 69. *Willd. Sp. Pl.* v. 1. 603. *Mart. Mill. Dict.* v. 4. *Sm. Fl. Brit.* 181. *Podr. Fl. Græc. Sibth.* v. 1. 97. *Ait. Hort. Kew.* v. 1. 242. *Juss. Gen.* 107. *Tournef. t.* 38. *Michaux Boreal-Amer.* v. 1. 81. *Pursh v. t.* 102. *Lamarek Illustr. t.* 60.—*Class and order, Tetrandria Monogynia. Nat. Ord. Stellata, Linn. Rubiaceæ, Juss.*

*Gen. Ch.* *Cal.* Perianth superior, of one leaf, four-toothed, very small, or none. *Cor.* of one petal, bell-shaped, four-toothed, or more frequently five-cleft, without a tube. *Stam.* Filaments four, awl-shaped, shorter than the corolla; anthers simple. *Pist.* Germen: inferior, twin; style thread-shaped, cloven at the top; stigmas two, capitate. *Peric.* Two smooth berries united into one. *Seeds* solitary, roundish, umbilicated.

*Eff. Ch.* Corolla of one petal, bell-shaped, superior. Berries two, combined, each with a single seed.

1. *R. tinctorum.* Dyer's Madder. *Linn. Sp. Pl.* 158. *Sm. Fl. Græc. Sibth. t.* 141. *Woodv. Med. Bot. t.* 68.—Leaves elliptic-lanceolate, annual, about six in a whorl, rough at the keel. Stem prickly.—Native of the south of Europe, flowering in June. *Root* perennial, widely spreading, much divided and branched at the top, succulent, its bark principally affording a scarlet dye. *Stems* herbaceous, annual, decumbent, widely spreading, branched, leafy, obtusely quadrangular, prickly, with little hooks at the angles.

## RUBIA.

gles. *Leaves* spreading, acute, an inch and half long, roughish above, narrowed at the base into a short, broad footstalk; at the margin and back of the rib rough with spines, which for the most part point backwards, but in a contrary way towards the tip. *Flowers* yellowish-green, in axillary, terminal, trichotomous, leafy or bracteated, rough panicles, longer than the leaves. *Berries* dark-purple.

The cultivation of this useful plant in Great Britain by no means keeps pace with the demand for it. That grown in Holland is the most esteemed by our dyers and calico-printers. Dr. Sibthorp tells us it is much cultivated in the neighbourhood of Athens.—Madder has the property of tinging, with its bright colour, not only the milk, but even the bones of such animals as feed upon it.

2. *R. chilensis*. Chili Madder. Willd. n. 2. "Molina Nat. Hist. Chili. 118." (*Rubiastrum, Cruciatæ folio et facie, vulgo Relbun; Feuillée Peruv. 60. t. 45.*)—Leaves annual, four in a whorl. Stalks axillary, solitary, single-flowered. Stem smooth.—Native of Chili, on mountains. Root perennial, much divided and spreading, affording a dye like the last. Stems round, slender, somewhat creeping. Leaves ovate, four together, forming a cross, rough and sticking to the clothes. Flowers axillary, solitary, stalked, white. Berries roundish, red.

3. *R. peregrina*. Wild English Madder. Linn. Sp. Pl. 158. Fl. Brit. n. 1. Engl. Bot. t. 851.—Leaves about four in a whorl, elliptical; shining and smooth on their upper side. Flowers five-cleft. Not uncommon in the south-west of England, among bushes, on a rich loamy soil, flowering in July, and ripening its berries about October.—Root perennial, red, or orange-coloured. Stems branched, diffuse, square, rough at the angles, perennial. Leaves four, rarely six together, evergreen, pointed, rough, with teeth at the margin, and nerves on the under side. Flowers in forked panicles, terminal, yellowish, always five-cleft and pentandrous, without a calyx. Berries black, one of them generally abortive.

It is remarked in the Flora Britannica, that *Rubia*, n. 708 of Haller, which has been confounded with this species, is unquestionably *R. tinctorum* of Linnæus, having ovato-lanceolate leaves, rough on the upper side, and flowers which are mostly four-cleft, destitute of a calyx.

4. *R. lucida*. Shining-leaved Madder. Linn. Syst. Nat. ed. 12. v. 2. 732. Willd. n. 4. Sm. Fl. Græc. Sibth. t. 142.—Leaves elliptical, evergreen, six in a whorl, smooth at the keel. Stem without prickles. Native of Majorca, and the islands of Zante and Cyprus. It flowers in July. Root perennial, branched, much divided at the crown. Stems rather shrubby, a little spreading, much branched, unarmed, clothed with roughish down; jointed, roundish, leafless and grey in the lower part; leafy and square in the upper. Leaves spreading, recurved, half an inch long, sessile, pointed, smooth on both sides, thickened at the margin, rough with spines pointing forwards. Flowering in axillary, numerous, trichotomous panicles, of a yellowish-green.

5. *R. fruticosæ*. Prickly-leaved Madder. Willd. n. 5. Jacq. Ic. Rar. t. 25.—Leaves evergreen, elliptical, ciliated; prickly at the margin. Stem shrubby, rough.—Native of the Canary islands, and flowering at Kew in September.—Stem woody, round, much branched, of a greyish-brown colour; the younger branches angular, very rough, green. Leaves from three to seven together, smooth, except at the edges and back of the rib. Flowers on axillary, short stalks, solitary or three together, pale yellow. Berries roundish, black, with purple pulp.

6. *R. angustifolia*. Narrow-leaved Madder. Linn.

Mant. 39. Willd. n. 6.—Leaves evergreen, linear, smooth on the upper side.—Native of Minorca, and introduced at Kew, in 1772, by M. Richard, where it flowers in July and August.—Stems diffuse, very rough, square. Leaves four or six in a whorl, linear, acute, their keel and margin fringed with small prickles, and rugged along the rib of the upper surface. Flowers yellow, flat, five-cleft.

7. *R. cordifolia*. Heart-leaved Madder. Linn. Mant. 197. "Pallas. It. v. 3. 715. t. L. f. 1." (*R. cordata; Thunb. Japon. 60.*)—Leaves perennial, four in a whorl, heart-shaped.—Native of the Cape of Good Hope, Siberia, China, and Japan; flowering at Kew in July.—Whole herb diffuse, or slightly climbing. Stem square, branched, with recurved prickles at the angles. Leaves four, rarely six, together, ovate, acute, revolute at the edge, rugged all over and dotted, on quadrangular stalks. Flowers white, in spreading, axillary, terminal panicles. Thunberg informs us that this species is used in Japan for dyeing.

8. *R. Brownei*. Brownian Madder. Michaux Boreal-Amer. v. 1. 81. Pursh 102. (*R. peregrina; Walt. Fl. Carol. 86.*—*R. subhirsuta scandens vel reclinata, foliis cruciatis floribus singularibus ad alas; Brown Jam. 141.*—*Valantia hypocarpa; Linn. Sp. Pl. 1491.*)—Leaves four in a whorl, oval. Flowers on stalks, solitary.—Found in shady woods from Carolina to Florida, and on the cool mountains of Jamaica. Stem herbaceous, from one to three feet high, loose, branched, grooved, rugged. Leaves sessile, small, entire, convex, hispid with hairs, on short downy stalks. Flowers axillary, small, yellow, like those of a *Galium*. Berries minute, tawny, or purplish, single-seeded.

RUBIA, in Gardening, contains plants of the hardy, herbaceous, perennial kind, of which the species mostly cultivated is the dyer's madder (*R. tinctorum*).

It may be noticed, that madder is so essential to dyers and calico-printers, that these businesses cannot be carried on without it.

*Method of Culture.*—The young plants of this kind are increased by off-sets or suckers, from the roots of the old plants in the spring, as April or the following month; which should be slipped off soon after they appear above ground, by opening the earth round the roots, and taking off the side suckers with as much root-part and fibres to each as possible, preserving the tops entire; which should be planted directly, in the manner directed below. The ground being well prepared by frequent deep ploughing, or trenching over, and the proper quantity of sets or suckers provided, they should, with a dibble, be planted in rows two feet asunder, and one distant in the row, putting each plant low enough in proportion to the length of its root, leaving most of the green top out of the ground, and closing the earth well about each set, as the work proceeds. Some set these plants in beds, three rows length-ways, at two feet distance, with wide alleys between bed and bed, in order for landing up the crowns of the roots two or three inches deep in winter. They shoot up into stalks the same year in either mode, but the roots require two or three years' growth before they are large enough for use; during which period they should be kept clean from weeds all the summer by broad-hoeing, in dry weather; and in autumn, when the stalks decay, cutting them down, and then slightly digging the ground between the rows, raising it somewhat ridge-ways along the rows of the plants, an inch or two thick over their crowns; or, if they are in beds, they may be landed up from the alleys to the same depth; the same culture being repeated till the autumn of the third year, when the roots will be fit for taking up for use. This is performed by trenching the ground the way of the rows, beginning at one end of it, and

and opening a two-foot-wide trench close along by the first row of plants, digging down to the depth of the roots to get them clean out to the bottom; then opening another trench close to the next row, turning the earth into the first; and so on, trench and trench, till the whole is taken up and removed.

It is found that, in the garden culture, these plants succeed best in a light rich deep soil; the roots are sometimes used fresh for dyeing, being prepared by washing and pounding; but commonly when designed for keeping, or to be sent to a distance, are dried in some covered airy shed; then all the mould being rubbed off, and the roots made sufficiently dry, are sold to those who manufacture them for use, if not performed by the cultivator; this consists in drying them in a kiln or some stove-house, &c. then thrashing them to beat off the outer skin, in order to separate it from the inner part of the root, as being of an inferior quality. The roots being then dried in a kiln about twenty-four hours, are removed to a mill or pounding-house, where they are pounded in a long hollow oaken block, with stampers kept in motion by the mill; and when thus reduced to powder, sifted, and put in casks, as may be more fully seen under the head Madder, in *Agriculture*.

But these plants are sometimes employed for variety in the borders or other open parts of gardens or pleasure-grounds, when of large extent.

RUBIA, in the *Materia Medica*, &c. See Madder.

RUBIA, in *Geography*, a town of Austria, in the county of Goritz, on the Vipava; four miles S.E. of Goritz.

RUBIACEÆ, in *Botany*, one of Jussieu's largest and most important natural orders of plants, which has grown out of the Linnæan *Stellatæ*, and is named from *Rubia*, a genus belonging to the latter. Linnæus, in subordinate sections of his *Stellatæ*, has indicated some genera, as akin to what more strictly appeared to him to constitute that order. But his ideas wandered between this tribe and the *Contortæ*, to which last he referred some genuine *Rubiaceæ*; as *Cinchona* and *Gardenia*. Jussieu, taking a more accurate and comprehensive view of the subject, has greatly extended the order, while he has, at the same time, better defined it than any preceding botanist. This order is the 57th of his series, the 2d of his 11th class. We refer the reader to DIPSACÆ for the characters of that class. *Cotyledons* two. *Flowers* monopetalous, superior. *Antbers* distinct; &c. The order of *Rubiaceæ* is thus defined.

*Calyx* of one leaf, superior, simple; its limb divided, or occasionally undivided. *Corolla* regular, mostly tubular, with a divided limb. *Stamens* definite, four or five, seldom more, inserted into the tube of the corolla, alternate with its segments, and equal to them in number. *Germen* inferior; style one, very rarely double; stigma generally double. *Fruit* in some cases of two lobes, or grains, each lobe single-seeded, not bursting, but having the appearance of a naked seed; in others a simple capsular or pulpy fruit, often of two cells, in each of which the seeds are either solitary or numerous; in a few instances there is but one cell, in some others many; the fruit, of whatever description, is either crowned with the permanent limb of the calyx, or marked with a rim, or scar, where the latter had been. The *corculum* is oblong, slender, inclosed in a large, horny, lateral albumen. *Stem* herbaceous, shrubby, or arboreous. *Leaves* in a few instances whorled, in most opposite, their footstalks generally connected at the base, through the medium of a simple pair of stipulas, or sometimes a fringed kind of sheath, embracing the stem or branch. Plants of this order are readily known, even without flowers, by their leaves or

*stipulas*. The shrubby and arboreous kinds are principally natives of tropical climates, where they greatly abound.

Section 1. *Fruit two-lobed, with two seeds. Stamens generally four. Leaves mostly whorled; stem almost uniformly herbaceous.*

*Sherardia, Asperula, Galium, Crucianella, Valantia, Rubia, and Anthospermum.*

SECT. 2. *Fruit two-lobed, with two seeds. Stamens four, rarely five or six. Leaves mostly opposite, connected by a fringed sheath; stem in general herbaceous.*

*Houstonia, Knoxia, Spermacece, Diodia, Galopina, Richardia, and Phyllis.*

SECT. 3. *Fruit simple, with two cells, and many seeds. Stamens four. Leaves opposite. Stem either herbaceous or shrubby. Hedyotis; Oldenlandia of Plumier and Linnæus, which is not distinct from Hedyotis, as we have shewn in its proper place; Carphalea of Jussieu, Lamarck Illustr. t. 59; Coccocypselum of Browne and Schreber; Gomozia; Manettia of Linnæus, for which Jussieu prefers Aublet's name Nacibea; Tontanea of Aublet, supposed to be Schreber's Bellardia; Petesia of Browne and Linnæus; Fernelia of Commerçon, Lamarck Illustr. t. 67; and Gatsbaa.*

SECT. 4. *Fruit simple, with two cells, and many seeds. Stamens five. Leaves opposite; stem often shrubby.*

*Randia*, which is a *Gardenia*; *Bellozia*; *Vireta*; *Macrocnemum*; *Bertiera* of Aublet and Schreber; *Dentella* of Forster; *Mussaenda*; *Cinchona*; *Tocoyena* of Aublet, Lamarck Illustr. t. 163; *Posoqueria* of the same authors, which is *Cyrtanthus* of Schreber; *Rondeletia*; *Genipa* of Plumier and Linnæus, which is a *Gardenia*; *Gardenia*; and *Portlandia*.

SECT. 5. *Fruit simple, with two cells, and many seeds. Stamens six, or more. Leaves opposite; stem shrubby or arboreous.*

*Coutarea* of Aublet, which is *Portlandia hexandra* of Linnæus; *Hillia*; and *Duroia*.

SECT. 6. *Fruit simple, with two cells and two seeds. Stamens four. Leaves opposite; stem for the most part shrubby.*

*Chomelia* of Jacquin; *Pavetta*; *Ixora*; *Couffurea* of Aublet; *Malanea* of the same, which is Schreber's *Cunningbania*; and *Antirrhæa* of Commerçon.

SECT. 7. *Fruit simple, with two cells and two seeds. Stamens five. Leaves opposite; stem shrubby or arboreous.*

*Chimarrhis* of Jacquin; *Chiococca*; *Psychotria*; *Coffea*; *Cantium* of Lamarck, which is a *Gardenia*; *Ronabea* of Aublet, Lamarck Illustr. t. 166; *Paderia*; *Coprosma*; and Aublet's *Simira*.

SECT. 8. *Fruit simple, with many cells, each containing a solitary seed. Stamens four, five, or more. Leaves opposite; stem often shrubby.*

*Nonatelia* of Aublet, which is scarcely different from *Psychotria*; *Laugeria*; *Erihalis*; *Psathura* of Commerçon, Lamarck Illustr. t. 260; *Myonima* of Commerçon, ibid. t. 68; *Pyrostria*, ibid. t. 68; *Vangueria*, ibid. t. 159; *Matthiola* of Plum. and Linn.; and *Guetarda*.

SECT. 9. *Fruit simple, with many cells, each containing many seeds. Stamens five, or more. Leaves generally opposite; stem either shrubby or herbaceous.*

*Hamelia*; *Patima* of Aublet, Lamarck Illustr. t. 159; and *Sabicea* of Aublet, which is Schreber's *Schwenkfeldia*.

SECT. 10. *Flowers aggregate upon a common receptacle; the fruit sometimes, but rarely, confluent. Leaves opposite; stem arboreous or shrubby, rarely herbaceous.*

*Miscella*; *Canephora* of Jussieu, Lamarck Illustr. t. 151; *Patabea* of Aublet; *Evea* of the same, also *Tupogonea*, both compre-

comprehended by Schreber under *Callicocca*; *Morinda*; *Nauclea*; and *Cephalanthus*.

SECT. 10. *Rubiaceous genera, with the nature of whose fruits Jusseu was not, as yet, sufficiently acquainted.*

*Seriffa* of Commerfon, Lamarck Illustr. t. 151, which L'Heritier named *Buchozia*; and found to have a berry with two seeds; *Pagamea* of Aublet, Lamarck Illustr. t. 88; *Faramea* of the same, ibid. t. 63; and *Hydrophyllax* of Linn. Suppl.

RUBICAN, in the *Manege*. A horse is said to be of a rubican colour, that is a bay, sorrel, or black, with a light grey or white upon the flanks, but so that this grey or white is not predominant there.

RUBICILLA AMERICANA, in *Ornithology*, a name given by Mr. Ray to the guiraticra, a Brazilian bird, of the bull-finch kind, very beautifully variegated with red, black, and grey.

RUBICOLA, a species of *Motacilla*; which see.

RUBICON, in *Geography*, a river of Italy, famous in Roman history, now a diminutive stream, and called by some Fiumefino, and by others *Pifatello* (which see), which enters the Adriatic about eight miles N. of Rimini.—Also, a department of Italy, composed of part of the Romagna. It contains about 105,000 inhabitants, who elect 12 deputies. The capital is Rimini.

RUBICULUS, in *Ichthyology*, a name given by Fingulus and some others to that species of fish which we call the *roach*. It is of the cyprinus kind, and is distinguished by Artedi under the name of the red-eyed cyprinus, with the tail and belly-fins red. See CYPRINUS.

RUBIELOS, in *Geography*, a town of Spain, in Aragon; 22 miles S. E. of Teruel.

RUBIERA, a town of Italy, in the department of the Panaro; five miles W. of Modena.

RUBIFYING, formed of *rubens*, *ruddy*, and *fo*, I become, in *Chemistry*, &c. the act of turning a thing red by force of fire, &c.

Red arsenic is common white arsenic rubified by a mixture of sulphur and copper.

RUBIGALIA, or ROBIGALIA, in *Antiquity*, a feast celebrated by the Romans, in honour of the god Rubigus, or the goddess Rubigo; to engage those deities to preserve the corn from blasting and mildews.

The Rubigalia were instituted by Numa in the eleventh year of his reign; and were held on the seventh of the calends of May, which is our twenty-fifth of April; being about the time when the blight or mildew, called by the Latins *rubigo*, uses to attack the corn.

Varro fixes it to the time when the sun enters the 16th degree of Taurus. Indeed the true time seems rather to have been on the 18th day before the equinox, and the true reason, because then Canicula, or the Little Dog, sets; which is esteemed a malific constellation.

Hence they sacrificed a dog to Rubigo: Ovid says, the entrails of a dog, and those of a sheep; Columella, only a sucking puppy. Festus insinuates, that the victim must also be red.

RUBIGO, or ROVIGO, a disease incident to corn, particularly called *mildew*.

The rubigo is a species of blight. See BLIGHT, and RUST of corn.

RUBIN of Antimony, in *Chemistry*, a kind of liver of antimony, made with equal parts of nitre and crude antimony detonated together, to which is afterwards added an equal quantity of common salt. It is also called *magnesia opalina*.

RUBIN, or *Roboan*, in *Geography*, a small island near the coast of Arabia, at the entrance of the straits of Babel-mandeb, near a projecting cape of the continent, and accessible by fording at low-water. Pilots are obtained here to navigate vessels through the straits, and to different ports in the Red sea.

RUBINELLI, GIOVANNI, in *Biography*, an Italian opera singer of the first class for voice, figure, action, and knowledge, arrived in England, from Florence, in April, 1786. His journey hither from Rome, where he sung during the carnival of this year, was not very propitious, as the weather was uncommonly inclement; and he was not only overturned in his chaise at Macon, in France, but after quitting the ship, in which he sailed from Calais to Dover, the boat that was to have landed him was overset near the shore, and he remained a considerable time up to his chin in water, to the great risk of his health, his voice, and even his life. The first time we meet with his name in the dramatic personæ of an opera is in "Caliroe," set by Sacchini, for Stutgard, in 1770, where he performed the part of second man. He seems to have continued at the court of Wirtemberg, in no higher station, several years, as Grassi and Muzio are named before him in the "Indice de' Spettacoli Teatrali." His name does not appear as first serious man in Italy till 1774, when he sung at Modena, in Paefello's "Alessandro nell' Indie," and Anfossi's "Demofonte." After this, he appeared as principal singer in all the great theatres of Italy, till his arrival in London. The first opera in which Rubinelli appeared in England was a *pasticcio*, called "Virginia," May the 4th. His own part, however, was chiefly composed by Angiolo Tarchi, a young Neapolitan, then advancing into eminence with great rapidity. Rubinelli is in figure tall and majestic, in countenance mild and benign. There is dignity in his appearance on the stage; and the instant the tone of his voice is heard, there remains no doubt with the audience of his being the first singer. It is a true and full contralto from C, in the middle of the scale, to the octave above. He sometimes, however, goes down to G, and up to F; but neither the extra low notes nor the high are very full. All above C is falset, and so much more feeble and of a different register from the rest, that we were uneasy when he transcended the compass of his natural and real voice. His shake is not sufficiently open; but in other respects he is an admirable singer. His style is grand, and truly dramatic. His execution is neat and distinct. His taste and embellishments are new, select, and masterly. His articulation is so pure and well accented, in his recitatives, that no one who understands the Italian language can ever want to look at the book of the words, while he is singing. His chest is so strong, and his intonation so perfect, that we have very seldom heard him sing out of tune. His voice is more clear and certain in a theatre, where it has room to expand, than in a room. He had a greater variety of embellishments than any singer we had heard, except Pacchierotti, who not only surpasses him in richness of invention and fancy, but in the native pathos, and touching expression of his voice. Yet Rubinelli, from the fulness of his voice, and greater simplicity of style, pleases a more considerable number of his hearers than Pacchierotti, though none perhaps, so exquisitely, as that singer used to please his real admirers. Rubinelli finding himself censured on his first arrival in England for changing and embellishing his airs, sung "Return, O God of Hosts," at Westminster Abbey, in so plain and unadorned a manner, that those who venerate Handel the most, thought him bald and insipid. Indeed,

we passed several appoggiaturas, which we remember Mrs. Cibber to have introduced, who learned to sing the air from the composer himself; and who, though her voice was a thread, and her knowledge of music very inconsiderable, yet from her intelligence of the words and native feeling, she sang this admirable supplication in a more touching manner, than the finest opera singer we ever heard attempt it; and Monticelli, Guadagni, Guarducci, and Pacchierotti, were of the number.

He remained here only one season; for in 1787 we find him singing at Brescia and Venice; and in 1788 he likewise performed in that city; in 1789, at Rome and at Milan; in 1790, at Genoa. He was succeeded in England by Marchesi.

RUBINUS VERUS, from *ruber*, a true carbuncle.

RUBIO, CAPE, in *Geography*, a cape on the N.W. coast of the island of Iviça. N. lat. 39° 5'. E. long. 1° 21'.

RUBIS, in *Ornithology*, guainumbi or humming-bird. See TROCHILUS *Cobubris*.

RUBLACEDA, in *Geography*, a town of Spain, in Old Castile; 18 miles S. of Frias.

RUBLE, in *Commerce*, a money of account in Russia, containing 100 copecks, or kopecks. The ruble is also divided into 10 grievens, 33½ altins, or 50 groschen; and the copeck is likewise divided into 2 denushkas, or 4 polushkas.

The gold coins are the imperial and half imperial, of 10 and 5 rubles; double and single ducats, formerly worth 4½ rubles and 2½ rubles, but raised in value, in 1764, the double ducat to 5 rubles 60 copecks, and the single to 2 rubles 80 copecks. The silver coins are rubles of 100 copecks; also poltins of 50 copecks; polpoltins of 25 copecks; double and single grieven of 20 and 10 copecks; and pieces of 5 altins or 15 copecks; and peyte-copecks, of 5 copecks each, now out of circulation.

Gold Coins.—The ruble, and also the double and half ruble, bear the same impressions as the ducat, viz. the head of the reigning emperor or empress, with the name and titles in Russian characters, thus translated: "Peter by the grace of God emperor, or Elizabeth by the grace of God empress, and sovereign of all the Russias;" but on the reverse of the ruble the value is written, "New coin, 2 rubles or 1 ruble;" and the half piece bears on its reverse the cypher of the empress Elizabeth, with the word "Poltina," which means half a ruble. These coins, as well as the ducats, are now nearly out of circulation.

The imperial has the head of the reigning sovereign, with name and title as above; reverse, a cross formed by five escutcheons, with the four figures of the year of coinage in the four angles; legend, "Imperial Russian coin, value 10 rubles;" and on the half imperial, "Value 5 rubles."

But the half imperials of Paul I. have on one side a square, with ornaments, containing the inscription, "Not unto us, not unto us, but unto thy name;" reverse, a cross and four crowns, with a capital I in the centre, and the figure 5 in the four angles of the cross.

Silver Coins.—The ruble has the head of the reigning sovereign, with the name and title as on the gold coins; reverse, a two-headed eagle crowned, with an escutcheon on its breast; legend, "New coin, value 1 ruble," or simply "Coin 1 ruble," and the date. Some rubles of Peter I. and Catherine I. bear on the reverse a cross and four crowns, with four I's, or four double II's in the four angles, and the date within the cross.

The ruble of Paul I. (1799, &c.) bears the same impressions as the half imperial of the same period, except that the legend on the reverse is "Coin, value 1 ruble."

The ruble of Alexander (1802) bears on one side the eagle and legend, as above; on the reverse, "Coin of the Russian empire, ruble," encircled with a branch of laurel, and one of oak, having a small crown at the top.

The poltina, or half ruble, bears the same impressions as the ruble, according to the period at which it was coined, except that the inscription contains the word *POLTINA*, instead of *RUBLE*; and the quarter ruble is marked *POLUPOLTINICK*.

The 20-copeck piece has the head, name, and title of the reigning sovereign, as above; reverse, a two-headed eagle, with the number 20 on its breast, and no legend. The 15-copeck piece bears the same impressions, but it is marked 15.

The 10-copeck piece has the two-headed eagle; reverse, the value of the piece, 10 *COPECKS*.

The 5-copeck piece has a Russian P, with a crown over it, and under which is an I; reverse, 5 *COPECKS*, and two laurel branches. Kelly's Universal Cambist.

*RUBRIC*, *RUBRICA*, in the *Canon Law*, denotes a title, or article, in certain ancient law-books; thus called, because written, as the titles of the chapters in our ancient Bibles are, in red letters.

*RUBRICS* also denote the rules and directions given in the Liturgy; for the order and manner in which the several parts of the office are to be performed.

They are called *rubrics* from the Latin *ruber*, red; because formerly printed in red ink, to distinguish them from the rest of the office, which was in black; as they still are in the Roman missals, &c.

The great rubric for the celebration of Easter, prescribed by the Nicene council, is to this purpose: Easter-day to be the Sunday which falls upon, or next after, the first full moon which immediately succeeds the vernal equinox. Dr. Wallis has a particular discourse on the ancient rubrics for the feast of Easter, in the Philosophical Transactions.

*RUBRICA*. See *REDDLE*.

*RUBUS*, in *Botany*, an ancient Latin word, certainly of the same origin as *ruber*, which appears to be the Celtic *rub*, red. (See *RHUS*, *ROSA*, and *RUBIA*.) The red hue, more or less prevalent, in various parts of the different kinds of Bramble, of which the present genus consists, readily accounts for the application of the above name.—Linn. Gen. 254. Schreb. 342. Willd. Sp. Pl. v. 2. 1080. Mart. Mill. Dict. v. 4. Sm. Fl. Brit. 541. Prodr. Fl. Græc. Sibth. v. 1. 349. Ait. Hort. Kew. v. 3. 267. Pursh 346. Juss. 338. Tourn. t. 385. Lamarck Illustr. t. 441. Gært. t. 73.—Class and order, *Icosandria Polygynia*. Nat. Ord. *Senticosæ*, Linn. *Rosaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, flattish, in five oblong, spreading, simple, permanent segments. *Cor.* Petals five, roundish or oblong, somewhat spreading, inserted into the calyx, and usually about the length of its segments. *Stam.* Filaments numerous, shorter than the corolla, inserted into the calyx; anthers roundish, compressed. *Pist.* Germens numerous, altogether superior; styles small, capillary, one springing from the side of each germen; stigmas simple, permanent. *Peric.* Berry compound, consisting of several roundish pulpy grains, each of one cell, collected into a convex head, hollow underneath, inserted upon a conical spongy permanent receptacle, and at length deciduous. *Seeds* solitary, oblong, compressed.

Obf. The separate juicy grains, which compose the general berry, are usually so attached to each other, that they cannot be separated without tearing. In *R. saxatilis* they are distinct. *R. Chamæmoris* is not, as Linnæus first thought, dioecious, but monoecious; Dr. Solander having

observed that the male and female flowers grow from one root, though on separate stems. Each flower of this species has indeed both stamens and pistils, though, in one or other flower, one part is imperfect.

Eff. Ch. Calyx in five simple segments. Petals five. Berry superior, composed of single-seeded grains, deciduous. Receptacle permanent.

This numerous genus partakes considerably of the beauty and elegance prevalent throughout the whole order of *Rosaceæ*, and is besides valuable, in many instances, for its wholesome and highly grateful fruit. The stem is most generally shrubby; sometimes herbaceous; more frequently trailing than erect; in some of the shrubby kinds biennial only, not perennial. Both stem, stalks, and even the ribs of the leaflets, in many of the shrubby species, are prickly. Leaves either lobed, digitate, pedate, or pinnate. Flowers either solitary, racemose, or paniced, red or white. Fruit black, blueish, red, or yellowish, often highly fragrant. Most of the species grow in cool climates, or mountainous situations. We have several to add to Willdenow's, which amount to 31 in number.

Section 1. *Stem woody*.

1. *R. roseifolius*. Rose-leaved Bramble.—Leaves pinnate, of five, or three, doubly serrated leaflets; green, and slightly downy, on both sides. Stem and footstalks prickly. Flowers solitary.—Sm. Plant. Ic. fasc. 3. t. 60. Willd. n. 1. Gathered by Commerfon in the isle of Mauritius, and communicated by Thouin to the younger Linnæus. We have also a fine specimen from sir Joseph Banks, without any account of its native country. The stem is shrubby, round, finely downy like the whole of the herbage, but no part is hoary or white. Prickles somewhat hooked, yellowish, rather small, copiously scattered over the stem and leaf-stalks. Leaflets usually five, ovato-lanceolate, taper-pointed, deeply, sharply, and doubly serrated; besprinkled with minute resinous particles, and of the same colour, on both sides. Stipulas in pairs on the base of each footstalk, linear-lanceolate, narrow and acute. Flowers solitary, stalked, either axillary, or opposite to the leaves, one of them terminal. Segments of the calyx ovate, taper-pointed, longer than the petals, densely downy, especially on the inner side. We know nothing of the fruit. The minute globular resinous particles, scattered, more or less copiously, over both sides of the leaves, seem peculiar to this species.

2. *R. fraxinifolius*. Ash-leaved Indian Bramble. Poir. in Lamarck Dict. v. 6. 242. (*R. moluccus parvifolius*; Rumph. Amboin. v. 5. 88. t. 47. f. 1.)—Leaves pinnate, of seven, or five, doubly serrated, parallel-veined leaflets; quite smooth on both sides. Footstalks prickly. Panicles terminal, smooth, widely spreading.—Gathered by Commerfon in Java. If we are right in the synonym of Rumphius, about which there seems little doubt, and which is certainly misapplied by Linnæus to his *R. parvifolius*, this species is common in Amboyna, growing in low situations near rivers. He says the fruit is red, but watery and insipid. The whole plant in our specimen is, except the downy inside of the calyx, quite smooth, and of so striking an appearance with its large ash-like leaves, marked with numerous, straight, parallel veins, that we cannot but wonder at its having so generally escaped the notice of Indian botanists. The stem is round, slightly, or not at all, prickly; though the footstalks, and now and then the rib of a leaflet, bear small hooked prickles. Stipulas almost setaceous. Panicles terminal, many-flowered, repeatedly compound, widely spreading; their stalks slender, unarmed, with several, scattered, oblong, smooth bractæes, toothed at the end. Segments of the calyx broadly ovate, with a long slender

slender point; partly downy on the outside, and densely so within. *Petals* not observed. *Fruit* of very numerous small grains. *Seeds* curiously reticulated or corrugated. Rumphius's figure is about half the size of nature.

3. *R. pinnatus*. Wing-leaved Cape Bramble. Willd. n. 2. Ait. n. 10.—“Leaves pinnate, of five or three rugose leaflets; smooth on both sides. Stem, footstalks, and flower-stalks prickly. Cluster terminal.”—Native country unknown. Willd. Cape of Good Hope, and island of St. Helena; from whence it was introduced by sir Joseph Banks in 1789. Aiton. A shrubby green-house plant, flowering in June and July. Branches villous, green, with hooked prickles. *Leaflets* ovato-lanceolate, green, sharply and doubly serrated; their mid-ribs, like the *footstalk*, prickly beneath. *Cluster* simple. *Flower-stalks* villous, very prickly. *Calyx* villous, longer than the *petals*. Willd. We presume the above authors both mean the same plant, though Willdenow is not cited by Aiton, and we have no specimens from either. We should suspect that the above-mentioned specimen of *roseifolius*, communicated by sir Joseph Banks, might be Mr. Aiton's *pinnatus*, were not the latter, as well as Willdenow's, said to have smooth leaves.

4. *R. australis*. New Zealand Bramble. Forst. Prodr. 40. Willd. n. 3.—“Shrubby. Flowers dioecious. Leaves pinnate, of five, or three, leaflets. Stem and footstalks prickly. Clusters simple, axillary.”—Native of New Zealand. Forster.

5. *R. rigidus*. Rigid Cape Bramble.—Leaves pinnate, of five, or three, partial-stalked leaflets; smooth above; very downy beneath. Stem downy, minutely prickly. Cluster terminal, twice compound.—Native of the Cape of Good Hope. We know it only by an unnamed specimen, from thence, in the Linnæan herbarium. The *stem*, *footstalks*, *flower-stalks*, *calyx*, and under side of the *leaves*, are all very densely clothed with fine, short, velvet-like down. *Leaflets* usually five, ovate, doubly and unequally serrated near an inch and a half long, each on a short, thick, partial stalk; the upper side green, smooth, striated with sunk ribs and veins, which project on the downy under side. *Stipulas* lanceolate, downy. *Flowers* numerous, rather small. *Calyx* with short thick points. The *petals* seem to be awl-shaped, and very small. We are unacquainted with the *fruit*.

6. *R. lasiocarpus*. Woolly-berried Bramble.—Leaves pinnate, of seven, or five, leaflets; smooth above; white and very downy beneath. Stem nearly smooth, with curved prickles. Cluster terminal, simple. Fruit downy.—Native of Myfore and the neighbouring hills. Sent by the Rev. Dr. Rottler, under the name of *Rubus indicus*. It appears to be no where described. At first sight the plant resembles our Raspberry, but the *leaflets* are generally seven, the odd one large, often three-lobed; their upper surface strongly striated with veins, which are occasionally hairy; the under very white and woolly, with yellowish, hairy ribs and veins. *Stipulas* awl-shaped, hairy. *Prickles* of the stem numerous, strong, a little curved. *Cluster* of few *flowers*, downy and prickly. *Fruit* clothed with dense, white, woolly down. *Seeds* reticulated. Possibly *R. apetalus* of Poiret, Lamarck Dict. v. 6. 242, may be allied to this.

7. *R. idæus*. Raspberry. Linn. Sp. Pl. 706. Willd. n. 4. Ait. n. 1. Pursh n. 1. Fl. Brit. n. 1. Engl. Bot. t. 2442. Woodv. Med. Bot. t. 138. Fl. Dan. t. 788. Ger. Em. 1272. Math. Valgr. v. 2. 357.—Leaves pinnate, of five, or three, ovate, rather angular leaflets, very downy beneath. Footstalks channelled. Stem with bristly prickles. Clusters terminal, lax, somewhat compound. Native of mountainous or stony woods and

thickets throughout Europe. Mr. Pursh says it occurs also in hedge-rows, from Canada to Pennsylvania; and Dr. Buchanan gathered what we cannot consider as a distinct species, in the woods of Nepaul. It flowers every where in April, May, or June, ripening fruit about six weeks after. The *stems* are erect, shrubby, though only biennial, with creeping perennial *roots*. They are pale brown, usually rough with small bristles rather than thorns; sometimes they are quite smooth. Lower *leaves* pinnate, with two pair of leaflets and an odd one; upper ternate only; leaflets broad-ovate, partly rhomboid, unequally and sharply serrated and cut, more or less pointed; greyish-green, and nearly smooth, above; white with dense cottony down beneath, like the *calyx* and *flower-stalks*. *Footstalks* rather downy, with a strong furrow along their upper side, prickly, like the *flower-stalks*. *Stipulas* setaceous. *Clusters* terminal, for the most part simple, lax, rather drooping. *Flowers* pendulous. *Calyx* with taper points, variable in length. *Petals* erect, obovate, white, small. *Fruit* crimson, of numerous pulpy grains, beset with the permanent styles. Its rich sweetness, and highly perfumed flavour, render this fruit generally agreeable, both recent and preserved. Raspberry jam is an acceptable present, even in India. There are several cultivated varieties, differing in size and luxuriance, as well as the colour of the berries, which are sometimes of an amber hue. Mr. Pursh says there are a number of wild varieties in America; a circumstance which we have not much remarked in Europe. There is usually a second crop of the fruit in gardens. The flavour of the wild kind is thought superior to the cultivated; at least in Wales.

8. *R. suberectus*. Red-fruited Bramble. Engl. Bot. t. 2572. Ait. Epit. Hort. Kew. 373. (*R. nesiensis*; Hall in Tr. of R. Soc. Edinb. v. 3. 20.)—Leaves pinnate, of seven, five, or three ovate leaflets; hairy beneath. Footstalks channelled. Stems ascending. Prickles minute, nearly straight. Flowers axillary and terminal, somewhat panicled.—This species, first observed in Scotland near Loch Ness, has since been found in other parts of that kingdom by Mr. George Anderson, F.L.S. as well as in Wales and Yorkshire. It is often intermixed with *corylifolius*, hereafter described, which it resembles in habit, especially in the pubescence, size, and hue of the foliage, though more naturally allied to *R. idæus*. The *stems* are biennial, not quite upright, brittle, reddish, nearly round, with spreading branches. *Prickles* scattered, small. *Leaves* light green on both sides; smooth above. *Panicles* racemose, rather lax, terminal and axillary. *Petals* larger and more spreading than in the last. *Calyx* finally reflexed. *Fruit* deep red, agreeable in flavour, later than the Raspberry, and perhaps for that reason, as Mr. Anderson suggests, not unworthy of cultivation.

9. *R. biflorus*. Two-flowered Bramble. Buch. MSS.—Leaves pinnate, of five or three acute jagged leaflets; hairy above; white and downy beneath: the odd one three-lobed. Stem and footstalks prickly. Flower-stalks downy, terminal, in pairs, single-flowered.—Native of wet situations, about banks of rivers in Upper Nepaul. Gathered by Dr. Buchanan at Chitlong, April 13, 1802. The *stems* are partly procumbent, branched, angular, a little zigzag, armed with scattered, straight prickles. *Leaves* on long, hairy, prickly stalks; their leaflets deeply serrated and jagged, usually five, the terminal one nearly sessile, more or less distinctly three-lobed, or even pinnatifid, though sometimes confluent with the two next, to as to make with them one deeply three-cleft leaflet; they are all very hairy, though green above; snow-white, with greenish hairy veins, beneath.

beneath. *Stipulas* linear. *Flowers* in pairs at the end of each branch, drooping. Segments of the *calyx* broad-ovate, very downy, with short naked tips. *Petals* broad and roundish, as long as the *calyx*. Of the *fruit* we are ignorant.

10. *R. strigosus*. Rough-stalked American Bramble. Michaux Boreali-Amer. v. 1. 297. Pursh n. 3. (*R. pennsylvanicus*; Lamarck Dict. v. 6. 246.)—"Leaves pinnate, of five, or three, oval, pointed leaflets; downy and white beneath. Stem erect, very bristly, without thorns. Flowers axillary, solitary; their stalks and calyx hispid."—Native of the mountains from Canada to Virginia, flowering in June and July; berries very agreeably flavoured. *Pursh*. The *branches*, *stalks*, and ribs of the *leaves*, *flower-stalks* and *calyx*, are all very hispid, but not prickly. *Michaux*.

11. *R. Commerfontii*. Commerfontian Bramble. Poiret in Lamarck Dict. v. 6. 240.—"Leaves pinnate, of seven, or five, leaflets, smooth on both sides. Stem prickly. Flowers terminal or axillary, nearly solitary. Calyx with long points."—Found by Commerfont in shady mountainous parts of the island of Java. Poiret says it has some relationship to *R. idæus*, but the *leaflets* are smaller, smooth on both sides, and the *flowers* larger. *Prickles* nearly straight, scattered. *Leaflets* narrow, cut and ferrated; the odd one sometimes lobed. *Footstalks* cylindrical, prickly. *Petals* white, roundish, scarcely longer than the *calyx*. *Fruit* reddish, the size of raspberries, but with a much less agreeable taste and smell. We have seen no specimen.

12. *R. occidentalis*. Virginian Raspberry. Linn. Sp. Pl. 706. Willd. n. 5. Ait. n. 2. Pursh n. 6. (*R. idæus*, fructu nigro, virginianus; Dill. Elth. 327. t. 247.)—Leaves ternate, taper-pointed, doubly ferrated; downy and white beneath. Footstalks nearly cylindrical; prickly and glaucous, like the stem. Prickles hooked. Clusters terminal, very prickly.—Native of rocky mountainous situations, from Canada to Carolina, flowering in May and June. Cultivated in Chelsea garden, before the year 1696, according to Plukenet. The *stem* is round, conspicuous for its peculiarly fine glaucous bloom, even in a dried state. *Leaves* all ternate, the side leaflets often furnished with a lateral notch, or lobe. *Prickles* on the *flower-stalks* remarkably numerous, and hooked. *Petals* small, white, commonly emarginate. *Fruit* black, sometimes red, sweetish, but not highly flavoured. *Seeds* wrinkled.

13. *R. triphyllus*. Three-leaved Japanese Bramble. Thunb. Jap. 215. Willd. n. 6.—Leaves ternate, rounded, cut and coarsely ferrated; entire at the base; downy and white beneath. Branches, footstalks, and flower-stalks hairy and prickly. Flowers somewhat racemose.—Gathered by Thunberg in Japan. *Stem* round, smooth, purplish, with slender, spreading, wavy *branches*, which are hairy and minutely prickly. *Leaflets* rounded, broad and abrupt, nearly smooth above, of a thin and pliant substance. *Flower-stalks* very shaggy just under the *calyx*, which is downy and white, with long taper points. *Petals* erect, obovate, crenate, with long claws. This species is in reality more akin to our Raspberry than any other, though perhaps sufficiently distinct. We have no knowledge of the fruit.

14. *R. tomentosus*. Velvet-leaved Bramble. Willd. n. 7. Sm. Prodr. Fl. Græc. Sibth. v. 1. 349. (*R. etneus*, trifolius rectus candicans ac pilosus; Cupan. Panphyt. v. 1. t. 149.)—Leaves ternate, or quinate, obovate, unequally ferrated, all over hoary, very soft and downy; paler beneath. Stem and footstalks with hooked prickles. Panicle downy, many-flowered. Bractæas linear-lanceolate, sometimes three-cleft.—Native of Germany, Switzerland, the neighbourhood of Constantinople, and the country about

mount Etna. We know no figure of this species, except in the very rare old work of Cupani, where it is extremely well represented, nor does any systematic author but Willdenow describe it. Botanists have most unaccountably confounded it with the common *R. fruticosus*, from which, and every other known species, it is distinguished by the peculiar and uniform soft pubescence of its *leaves*, equalling that of the Marsh Mallow. The *leaflets* vary in shape, but are always contracted towards their base. They are usually three, the lateral ones sometimes lobed at the lower edge. We have a specimen with five distinct leaflets, the lowermost pair smallest, growing out of the partial footstalks of the next. The *stem* is angular, downy, with many uniform, rather small, strongly hooked prickles, such as occur also on the footstalks. *Flowers* large and abundant, with obovate, white, spreading *petals*, twice as long as the *calyx*, whose segments are ovate, finely downy, with small points. The *bractæas* are more pale and membranous than in *fruticosus*. *Stipulas* linear, very narrow, hairy. This species is unknown in England, either wild or cultivated.

15. *R. euneifolius*. Wedge-leaved American Bramble. Pursh n. 5. (*R. parvifolius*; Walt. Carol. 149.)—"Leaves digitate, of three or five obovate-wedge-shaped leaflets; unequally toothed upwards, plaited, entire at the margin, revolute; downy beneath. Stem, footstalks, and flower-stalks downy, with scattered recurved prickles. Clusters terminal, panicled; the partial flower-stalks divaricated, and almost naked."—In sandy fields and woods, from New Jersey to Carolina, flowering in June and July. A straggling briar, of a grey aspect; the *berries* hard and dry. *Pursh*. Not having seen this plant, we have given, as nearly as possible, a translation of Mr. Pursh's specific character, though we do not quite understand what regards the *leaves*.

16. *R. ellipticus*. Oval-leaved Indian Bramble.—Leaves ternate, elliptical, finely ferrated; downy and hoary beneath: the lower ones simple, somewhat three-lobed. Stem and footstalks hispid, downy, and prickly. Panicle dense, hairy.—Gathered by Dr. Buchanan, in January and April 1802, about the stony banks of rivulets in Nepal. This *shrub* is ten or twelve feet high, with long, climbing, angular, zigzag, leafy *branches*, not only clothed with soft down, and copious rigid prominent bristles, but also bearing scattered, hooked, strong, though not large, prickles. The *footstalks* are similarly furnished. *Leaflets* much resembling those of a common Provins Rose in shape and ferratures, but rather larger, and only three to each leaf; smooth above; their under surface grey or whitish with fine down; the veins parallel, straight, strongly marked. *Stipulas* setaceous. The lower *leaves*, and small axillary ones, are simple, occasionally three-lobed. *Panicle* terminal, dense, shorter than the *leaves*, compound. *Flowers* not very numerous. *Calyx* downy. *Petals* white, longer than the *calyx*. *Berries* yellow, pleasantly flavoured. *Seeds* wrinkled, numerous.

17. *R. hispidus*. Bristly American Bramble. Linn. Sp. Pl. 706. Willd. n. 8. Ait. n. 3. Pursh n. 7.—Leaves ternate, strongly ferrated, smooth on both sides. Stems trailing, round, hispid as well as the footstalks. Clusters terminal, slender, somewhat hispid, of few flowers.—Gathered in Canada by Kalm, whose specimen is before us. The *stems* are very long and trailing, clothed with copious, brown, reflexed bristles, without prickles, as are also the *footstalks*. *Leaflets* of a shining green; the middle one obovate; the others dilated, and often lobed at the outer edge; all acute, unequally ferrated. *Flowers* few, with linear,

## RUBUS.

linear, sometimes three-cleft, *bracteas*. *Berries* of few grains, with large wrinkled *seeds*. Perhaps this ought to be arranged among the herbaceous species, near *saxatilis* hereafter described.

18. *R. trivialis*. Common American Dewberry. Michaux Boreali-Amer. v. 1. 296. Pursh n. 8.—“Leaves ternate, or quinate, oblong-oval, acute, unequally ferrated, rather downy. Stems trailing. Flower-stalks solitary, elongated, rough, like the footstalks, with recurved prickly bristles. Stipulas awl-shaped. Petals obovate, thrice the length of the calyx.”—Common in old fields, from New England to Carolina, blossoming in May and June. *Flowers* large. *Berries* black, large, very agreeably flavoured, known by the name of Dewberries. *Pursh*.

19. *R. flagellaris*. Long Trailing American Bramble. “Willd. Enum. 549.” Pursh n. 9. (*R. trivialis*; Ait. n. 7. *Pursh*.)—Leaves ternate, unequally ferrated, smooth on both sides. Stems trailing, round, beset, like the footstalks, with recurved prickles. Clusters terminal, lax, slender, downy, of few flowers.—Native of fields and sandy woods, from Virginia to Carolina, flowering in June and July. *Pursh*. Very nearly akin to *R. hispidus*, n. 17, but the *leaves* are smaller, and the *stem* is rather prickly than bristly. The hooked prickles on the *footstalks* are few, and widely feathered. *Petals* more orbicular than in the last; whether they accord with those of *hispidus*, we have not materials to determine; but we are greatly inclined to think the present is but a variety of that species.

20. *R. inermis*. Smooth American Bramble. “Willd. Enum. 548.” Pursh n. 10. (“*R. hispidus*; Walt. Carol. 149?”)—“Leaves ternate, ovate, acute, unequally ferrated; downy beneath; the lateral leaflets somewhat cut. Stem, footstalks, and flower-stalks unarmed. Stipulas narrow-awl-shaped.”—Native of Pennsylvania. We have seen no specimen of this species, nor did Mr. Pursh himself meet with it in America.

21. *R. parvifolius*. Small leaved Indian Bramble. Linn. Sp. Pl. 707. Willd. n. 9; excluding the synonym of Rumphius, which has no affinity to this species, but rather belongs to our *fraxinifolius*, n. 2. Leaves ternate, wrinkled, rounded, cut, and crenate; somewhat hairy above; downy and snow-white beneath. Branches and footstalks downy, with short hooked prickles. Stem round. Panicles downy and hairy, of few flowers.—Gathered by Osbeck in China. A miserable specimen from him, without flowers, exists in the Linnean herbarium; but we have very complete ones collected by Dr. Buchanan, at Chitlong in Nepal, April 10, 1802. Their first appearance accords very much indeed with our Common Raspberry, but the *leaflets* are all ternate, rounded, not pointed, crenate rather than ferrated, as well as more wrinkled; and their upper surface, though green, is clothed with extremely soft hairs, feeling like velvet. The *flowers*, though few together, are paniced rather than simply racemose; their very woolly *calyx* is destitute of long points; and their *stalks* are hairy as well as woolly. We have no account of the *fruit*. The short, but strong and hooked, *prickles* moreover afford an essential distinction between this species and *R. ideus*.

22. *R. sanctus*. Bramble of the Holy Land. Schreb. Dec. 15. t. 8. Willd. n. 10. (*R. creticus* triphyllus, flore parvo; Tourn. Cor. 43. Poccocke's Trav. v. 2. pt. 2. 190.)—Leaves ternate, or simple, downy and white beneath. Branches and footstalks downy, with hooked prickles. Stem angular. Panicles downy, many-flowered. Native of Crete and Palestine. This has a general resemblance to our British *R. fruticosus*, but has smaller, more rounded,

and fewer *leaflets*. The *flowers*, and whole plant, are also of smaller dimensions. We do not however profess to be well acquainted with the limits of these two species, nor has the present one been properly investigated.

23. *R. jamaicensis*. Jamaica Bramble. Linn. Mant. 75. Willd. n. 11. Swartz Obf. 205. (R. n. 1; Browne Jam. 242. *R. foliis longioribus, subtus molli lanugine obductis et incanis, flore et fructu minoribus*; Sloane Jam. v. 2. 109. t. 213. f. 1.)—Leaves ternate, or pedato-quinatae, pointed, sharply ferrated; white and finely downy beneath. Branches, footstalks, and flower-stalks downy, with hooked prickles. Panicles lax.—Native of Jamaica; frequent in the mountains of St. Mary's, and those beyond mount *Diable*, towards St. Ann's, but seldom seen in any other part of the island. *Browne*. Sloane justly remarks, that any arguments in favour of the coldness of the air in parts of Jamaica, or Hispaniola, where this bramble occurs, prove nothing, because it is a different species from our European one. Possibly however they may be more nearly related than he was aware. The pubescence of the back of the *leaves*, though very fine, soft, and white, is often approached in these particulars by that of our *fruticosus*, even on the same stem, with leaves that are almost green underneath. The insertion of the stalks of the fourth and fifth *leaflets*, when present, upon those of the next pair, making a pedate leaf, is characteristic of the Jamaica Bramble, but even this is occasionally to be detected in our's. The *flower* and *fruit* are said to be smaller than in *fruticosus*. In the Linnean specimen the *flowers* are double, quite as large as those of the latter. The ribs of the *leaflets* are prickly in both; nor are the ferratures at all more deep in one than the other.

24. *R. roseus*. Red-flowered Peruvian Bramble. Poir. in Lamarek Dict. v. 6. 245.—Leaves ternate, or simple, smooth. Stipulas oval, obtuse. Flowers axillary, nearly solitary. Calyx smooth, slightly fringed. Stem, flower-stalks, footstalks, and ribs of the leaves very prickly.—Gathered by Dombey in Peru. The *branches*, according to Poir. are woody, striated, smooth, zigzag, prickly. *Leaves* very large, mostly ternate, oval or lanceolate, unequal, smooth on both sides; a little paler beneath. The terminal *leaflet* is four or five inches long, and three broad. *Stipulas* large, almost half embracing the stem. *Flower-stalks* long, plentifully furnished with strong, reddish, recurved prickles. *Calyx* large, with bluntly-pointed segments, a little fringed at the margin. *Petals* rose-coloured, roundish, shorter than the calyx, furnished with claws. We have seen no specimen, but the above description leaves no doubt of this being a most distinct species.

25. *R. urticifolius*. Nettle-leaved Peruvian Bramble. Poir. in Lamarek Dict. v. 6. 246.—Leaves ternate, or simple, ovate, sharply ferrated; silky beneath. Stem, flower-stalks, footstalks, and ribs of the leaves densely hispid and somewhat prickly. Panicles compound, many-flowered. Calyx silky.—Gathered at Lima by Dombey, from whom we have a specimen. This is said to be of very lofty growth. The *branches* are angular, remarkable, like all the *stalks*, for a dense rusty coating, resembling coarse plush, among which some few short hooked prickles are interperled. The *leaflets* are large, densely, sharply, and rather unequally ferrated; in form ovate, or somewhat elliptical; their upper side green, minutely downy; the under very densely covered with shining silky pubescence, which is said by Dombey to be of a silvery whiteness when fresh, though rather tawny in our specimen. *Stipulas* almost tetaceous. *Panicle* large, dense, many-flowered. *Bracteas* ovate, silky externally, as well as the *calyx*. *Petals* minute, white.

## RUBUS.

white. *Fruit* black, of numerous grains, with reticulated seeds.

Mutis sent Linnæus a specimen from Santa Fé, which agrees in every essential particular with that of Dombey, except the *leaflets* being smaller, and in some instances five in number.—The specific name does not appear to us very appropriate; *holosericeus* would have been better, for we have met with nothing of so silky an aspect in the genus besides.

26. *R. cæsius*. Common Dew-berry. Linn. Sp. Pl. 706. Willd. n. 12. Ait. n. 4. Fl. Brit. n. 2. Engl. Bot. t. 826. Bulliard t. 381. (*R. minor*, fructu cæruleo; Bauh. Hist. v. 2. 59.)—Leaves ternate, hairy beneath; the lateral leaflets lobed externally. Stem prickly, prostrate, glaucous. Calyx embracing the fruit.—Native of Europe, in groves and bushy places; not rare in England; about shady hedges and the borders of fields, flowering in June and July, bearing fruit throughout August and September. The stems are round, weak and trailing, beset with slender slightly curved prickles, and conspicuous for a vivid glaucous bloom, easily rubbed off. Though woody, they are only annual, or at most biennial. *Leaflets* three, of a broad, rounded, ovate figure, acute, sharply and doubly serrated, light green; downy and a little paler, but not hoary, beneath; the lateral ones sessile, generally lobed on the outside. *Footstalks* prickly and downy. *Stipulas* lanceolate. *Flowers* few together, in slender, terminal or axillary, prickly panicles. Segments of the *calyx* ovate, or obovate, long-pointed, downy, spreading the *flower*, closed about the *fruit*, which last character is neglected in Bulliard's, otherwise characteristic, plate. *Petals* obovate, longer than the calyx, spreading, waved and crumpled, white, rarely reddish. *Fruit* of few and rather large grains, black with a bright blue tinge, like a plum; its flavour very agreeably acid, though not perfumed, and destitute of the mawkish flavour of the common Black-berry.

27. *R. corylifolius*. Hazel-leaved Bramble. Fl. Brit. n. 3. Engl. Bot. t. 827. Ait. n. 5. (*R. major*, fructu nigro; Schmidel Ic. t. 2. *R. montanus repens*, sarmentis longissimis et rotundis, spinis tenuissimis exasperatis, amplo coryli folio, flore albo, fructu nigro crassiore; Mich. Hort. Florent. 82. Till. Pis. 149?)—Leaves quinate, or ternate, rounded, hairy beneath; the lateral leaflets sessile. Prickles straightish. Calyx of the fruit reflexed.—Native of England, Germany, and probably of Italy. We cannot discover that Dr. Sibthorp met with this species in Greece. Dillenius seems to hint at it in his edition of Ray's *Synopsis*, 467, as differing from the common bramble, in having "earlier, larger, and white blossoms," which is correctly true. Mr. Crowe, ever attentive to the useful parts of botany, was led to distinguish our *corylifolius*, by observing that thatchers rejected the *stems*, on account of brittleness, and selected the true *fruticosus* to bind down their thatch, that species being truly shrubby and perennial; while the *stems* of the present are, like those of the Raspberry, biennial, and far more brittle than *fruticosus*. They are moreover roundish, all the prickles nearly straight, not hooked. The *leaflets* are large, pliant, doubly serrated, always of a bright green on both sides; hairy, but never white or cottony, beneath. Some of them so exactly resemble the leaves of a hazel, that we have puzzled good botanists to distinguish one from the other. The *flowers* appear early in July, and are white, forming an oblong cylindrical *panicle*. *Fruit* earlier, of a browner black, of rather fewer grains, and more gratefully acid than in *fruticosus*, being intermediate, as it were, between the Dew-berry and Common Black-berry. Its

reflexed *calyx* distinguishes it readily from the former. Our *corylifolius* is supposed to be the *fruticosus* of Hoffmann's German Flora, and perhaps of many other botanists. Willdenow has it not.

28. *R. fruticosus*. Common Bramble, or Black-berry. Linn. Sp. Pl. 707. Willd. n. 13. Ait. n. 6. Fl. Brit. n. 4. Engl. Bot. t. 715. Mill. Illustr. t. 45. (*R. major*, fructu nigro; Bauh. Hist. v. 2. 57. *Rubus*; Ger. Em. 1272. Camer. Epit. 751.)—Leaves mostly quinate, downy beneath; leaflets stalked. Stem angular, beset, like the footstalks and flower-stalks, with hooked prickles. Calyx of the fruit reflexed.—Common in hedges and thickets throughout Europe; flowering with us in July and August, and ripening fruit in September and October. Dr. Sibthorp found this species extremely abundant in Greece, and conceived it to be, as generally supposed, the true *Berberis*; or Bramble, of Dioscorides, the same name being given to it by the modern Greeks. The *stem* is truly shrubby and perennial, long and arching, purplish, strongly angular, armed with very powerful hooked prickles, such as occur, of a smaller size, on the stalks and ribs of the *leaves*, as well as on the *flower-stalks*. The *leaflets*, usually five, are of a narrower, more oblong, and pointed form than the last; dark green above; very white and cottony beneath; though specimens may occasionally be found which have, on one and the same branch, such white-backed leaves, with others that are pale green, or barely hoary. All the *leaflets* have commonly very considerable partial footstalks, the outermost more or less combined with the next. The *flowers* in long, cylindrical, compound, dense, and rigid panicles, are of an elegant bluish or rose-colour, seldom white. *Calyx* downy, moderately pointed, always reflexed both in flower and fruit. *Berry* of very numerous crowded grains, of a violet black when ripe, with a sweet but mawkish taste, acceptable only to children, whose

"Pretty lips with black-berries,  
Are oft besmeared and dyed."

There is a supposed variety of *R. fruticosus* with jagged leaves, green beneath, and double white flowers.

29. *R. villosus*. Hairy American Black-berry. Ait. n. 8. Willd. n. 14. Pursh n. 2.—Leaves quinate, or ternate, ovate-oblong, taper-pointed, sharply serrated, finely hairy on both sides. Stem and footstalks hispid, and somewhat prickly. Clusters simple, lax, hairy, and glandular; sometimes leafy.—In old fields and commons, from New England to Carolina, frequent, flowering in June and July, and known by the name of Black-berries. *Pursh*. It appears to have been introduced into the gardens of England and France about the same time, near 40 years ago. In the latter it was called *R. vulpinus*. The *leaves* are rather large, properly consisting of five leaflets, green on both sides, of which the terminal one has a very long partial stalk, and the two hindmost very short ones, all the partial stalks radiating from one point. In some of the upper leaves the lateral leaflets are combined for almost their whole length; the next leaf to these is ternate; and the uppermost of all simple, diminishing into a leafy bractea under each *flower-stalk*, but still accompanied by *stipulas*. The *flowers* are rather small, and seem to be white.

30. *R. canadensis*. Purple-stalked Canada Bramble. Linn. Sp. Pl. 707. Willd. n. 15. Pursh n. 4.—Leaves digitate, of from ten to five, or three, lanceolate, taper-pointed, sharply serrated, partial-stalked leaflets, smooth on both sides. Stem without prickles.—In rocky barren woods of Canada and New England, flowering in June and July.

## RUBUS.

The stem and old branches are purple. *Pursh*. This is very unlike all the rest, having so many leaflets, all smooth on both sides; paler beneath, where they are marked by strong, prominent, parallel veins. *Footstalks* channelled, purplish, nearly or quite smooth. *Stipulas* fetaceous. *Flowers* in simple, dense, terminal, downy clusters, with ovate, pointed, smooth bractes. *Calyx* of the fruit reflexed, slightly downy. *Berries* of a few large grains, with wrinkled seeds. *Linnaeus* by mistake cites the very same figure of Miller, which a few lines below, he properly refers to *R. odoratus*. This error Willdenow implicitly copies, without doubt or remark.

31. *R. spectabilis*. Elegant American Bramble. *Pursh* n. 11. t. 16.—Leaves ternate, ovate, acute, doubly serrated; downy beneath. Stem smooth and unarmed. Stalks single-flowered, solitary. Petals ovate.—Gathered by Mr. Menzies on the north-west coast of America, and by governor Lewis on the banks of the Columbia; flowering in April and May. *Pursh*. An elegant shrub, four or five feet high. Stem smooth, destitute of prickles; the branches slender, round, very smooth. Leaves large, on downy, channelled, occasionally somewhat prickly stalks, ternate; the lateral leaflets sessile, oblique at the base, and lobed at the outer side. *Stipulas* awl-shaped. *Flowers* as large as in the following species, of a full and rich crimson. Segments of the calyx downy, oblong, with short points. Petals full twice as long as the calyx.

32. *R. odoratus*. Flowering Raspberry. *Linn. Sp. Pl.* 707. *Willd. n.* 16. *Ait. n.* 9. *Pursh n.* 12. *Curt. Mag. t.* 323. *Mill. Ic. t.* 223. *Cornut. Canad.* 149. t. 150.—Leaves simple, with three or five acute lobes. Stem erect, hispid, unarmed. Corymbs terminal, spreading, hispid and glutinous. Petals nearly orbicular. Calyx with linear leafy points.—This, according to Mr. Pursh, is found in the woods of Canada, and on the Alleghany mountains, from New York to Carolina, blossoming in June and July. In the gardens of Europe it has been cultivated for above a century, being, though a greenhouse plant in Sweden, perfectly hardy with us, and generally admired in shrubberies for the beauty of its copious, large, crimson flowers, with singularly white stamens; as well as for the cedar-like fragrance of its glutinous, rough, brown flower-stalks and calyx. The stems are a yard high, or more, biennial like *R. idaeus*. Leaves ample, serrated, roughish, of a fine green. The fruit is scarcely ever formed in England. Miller describes it as reddish, insipid, of numerous small grains. Mr. Pursh says “the berries are yellow, of a very fine flavour and large size, but scarcely ever produced in the gardens.”

33. *R. alceaefolius*. Hollyhock-leaved Bramble. *Poiret in Lamarck Dict. v.* 6. 247.—Leaves simple, somewhat palmate, sharply serrated, rugose; downy beneath. Clusters axillary and terminal, prickly. Bractes in many capillary segments. Calyx very hairy, inflated. Branches angular. Gathered by Commerçon in Java. The stems are about as tall as *R. idaeus*, divided into very hairy, almost quadrangular, branches, furnished with reddish prickles. Leaves lobed, almost palmate, sharply toothed, very broad; rough and wrinkled, but not hairy, on their upper surface; downy beneath, with yellowish reticulated veins. Footstalks, as well as the principal ribs of each leaf, prickly. Clusters short, prickly, very hairy. Bractes hairy, divided into numerous capillary segments. Calyx inflated, almost globular, divided half way down into five oval segments; white within; clothed externally with dense, tawny, woolly hairs. Petals roundish, white, soon falling. We know nothing of this species but from *Poiret's* description, which

is very clear and well marked. We have altered his specific character by that description, for the purpose of contrasting its essential particulars with the following.

34. *R. rugosus*. Rugged-leaved Bramble.—Leaves simple, heart-shaped, roundly lobed, crenate, rugose; downy beneath. Clusters axillary and terminal. Bractes ovate, cut. Calyx very hairy, branches round, prickly.—Gathered by Dr. Buchanan, July 18, 1802, at Sembu, in Upper Nepal, where it is called, in the Parbutie language, *Jogi Aysbalu*, and by the Nawars *Cumbatafsi*. The stem is climbing, with round, downy branches, armed with small, scattered, hooked prickles. Leaves as broad as the palm of the hand, heart-shaped, acute, with about five or seven rounded, sharply crenate, rather shallow lobes; the upper side green, tessellated with numerous wrinkles, rather hairy; the under white and downy, reticulated with innumerable veins. Footstalks round, downy and prickly, as well as the principal ribs. Stipulas oblong, ovate, toothed, downy. Clusters short and dense, chiefly axillary, not so long as the footstalks, of few flowers; the terminal one larger. Bractes broader than the stipulas, hairy, slightly cut or toothed. Flowers large. Calyx densely covered with long silky hairs; its segments ovate, acute, recurved, downy within. Petals white, erect, almost as long as the calyx, ovate, obtuse, finely toothed, furnished with claws. Fruit red. The round branches, less divided leaves, and more entire bractes, seem to render this essentially distinct from *Poiret's alceaefolius*, to which it is evidently next akin.

35. *R. tiliaceus*. Lime-leaved Bramble.—Leaves heart-shaped, rounded, acute, sharply crenate, very obscurely lobed; white and downy beneath. Clusters axillary. Segments of the calyx lanceolate, downy. Stem and footstalks round, downy, slightly prickly. Gathered by Dr. Buchanan at the same place as the last, June 2, 1802. The leaves somewhat resemble those of the American *Tilia alba*. They are sometimes nearly orbicular, but generally have indications of a slight lobe at each side; the upper surface is green, naked, and tolerably even; the under clothed with very soft fine white down. All the stalks, like the calyx, are more cottony than silky. The latter is deeply divided, spreading, or in some degree recurved. Petals small, spatulate. Seeds wrinkled. The clusters are more lax, and the flowers very much smaller than in *R. rugosus*. Small dispersed prickles may be felt, rather than seen, here and there on the downy branches and footstalks. The bractes are small, woolly, deeply jagged.

36. *R. moluccanus*. Molucca Bramble. *Linn. Sp. Pl.* 707. *Willd.* 17. (*R. moluccus latifolius*; *Rumph. Amboin. v.* 5. 88. t. 47. f. 2.)—Leaves simple, heart-shaped, somewhat lobed, crenate; white and downy beneath. Clusters axillary and terminal, aggregate. Bractes deeply palmate. Calyx silky. Stem and footstalks round, downy, prickly.—Native of Amboyna and the Molucca islands. Very nearly allied to the three preceding species, but the leaves are more elongated and acute than in any of them, with a pair of rounded, more or less distinct, lateral lobes towards the base. The deeply palmate, or digitate silky bractes seem nearly to agree with those of the *alceaefolius*. The flowers are plentiful. Calyx silky, with deep, lanceolate, taper-pointed segments. Petals obovate, crenate. Fruit red, eatable, but rather insipid.

37. *R. microphyllus*. Small-leaved Japan Bramble. *Linn. Suppl.* 263. (*R. palmatus*; *Thunb. Jap.* 217. *Ki Itzigo*; *Kämpf. Amœn. Exot.* 787.)—Leaves simple, heart-shaped, obtuse, three-lobed, smooth. Stem and footstalks prickly. Flowers solitary. Outside of the calyx naked. Gathered by *Thunberg*, in hilly places, between Miacó and Quana in Japan,

Japan, flowering in April. The *stem* is shrubby, erect, two or three feet high. *Branches* round, wavy, smooth, purplish, beset with prominent, rather ascending, scattered prickles. *Leaves* several together from each lateral bud, on shortish, channelled, rather prickly *stalks*, heart-shaped, rounded, sharply crenate, more or less three-lobed, strongly veined and somewhat plaited, smooth on both sides; paler beneath; their length about an inch. *Flowers* solitary from each bud, stalked. *Calyx* smooth and angular at the outside; downy within; its segments lanceolate, acute. *Petals* twice as long as the calyx, obovate, white, wrinkled, with long claws. *Fruit* yellow, very well flavoured.

38. *R. incisus*. Cut-leaved Japan Bramble. Thurb. Jap. 217. Willd. n. 19.—Leaves simple, heart-shaped, obtuse, cut, smooth. Footstalks with hooked prickles. Stem prickly. Flowers solitary. Outside of the calyx naked.—Native of Japan. We have seen no specimen. This species seems, from Thunberg's description, very near the last, differing chiefly in the divisions of the *leaves*.

We here find in Willdenow the *R. japonicus*, Linn. Mant. 245. Suppl. 263. This the Linnæan herbarium shews to be no other than *Corchorus japonicus* of Thunberg, a beautiful shrub, now becoming common in our gardens, where it is quite hardy. The double yellow *flowers* are much admired. Linnæus, by his specimen, supposed the *petals* to be white. He knew nothing of the *fruit*, and judging by the habit, was not inexcusable in referring the plant to *Rubus*. See CORCHORUS, n. 12.

39. *R. corchorifolius*. Corchorus-leaved Bramble. Linn. Suppl. 263. Willd. n. 21. (*R. villosus*; Thunb. Jap. 218.)—Leaves simple, oblong-heart-shaped, pointed, ferrated, somewhat hairy. Stem round, downy, prickly. Flowers solitary. Outside of the calyx hairy. Native of Japan, between Miaco and Jedo, flowering in April. The *stem* is shrubby and upright, finely downy, with a few distant, slightly recurved, prickles. *Footstalks* hairy and prickly. *Leaves* longer, and much more pointed, than in *microphyllus* or *incisus*, with finer more copious ferratures; their ribs and veins especially hairy. *Flowers* on the young branches, stalked, solitary, much like the two last species, but the calyx is both downy and hairy on the outside. Nothing is said of the *fruit*. The *leaves* are described by Thunberg as elegantly plaited before they fully expand.

40. *R. elongatus*. Long-clustered Bramble. Sm. Plant. Ic. t. 62. Willd. n. 22.—Leaves simple, heart-shaped, pointed, doubly crenate; white and downy beneath. Panicle elongated, racemose. Segments of the calyx rounded, obtuse. Gathered by Commerfon in Java. The *branches* are round, downy, with minute dispersed prickles. *Leaves* very smooth and even on the upper side; their margin furnished with a row of broad shallow notches, or ferratures, with small, rather acute, intermediate ones. *Panicle* terminal, long, lax, zigzag, finely downy or silky, in every part, as well as the *calyx*. *Braëtas* oblong, jagged at the end, deciduous. *Flower-stalks* short and thick, aggregate, clustered, or somewhat umbellate. Segments of the *calyx* remarkably rounded. *Petals* orbicular, white. *Fruit* red.

41. *R. paniculatus*. Spreading Panicle Bramble.—Leaves simple, heart-shaped, pointed, slightly lobed, sharply and finely crenate; white and downy beneath. Panicle twice compound, spreading. Segments of the calyx ovate, taper-pointed. Gathered by Dr. Buchanan, at Narain hetty, in Nepaul, Nov. 18, 1802. The round, downy *branches*, with small scattered prickles, agree with the last, as well as with *moluëcanus*, *rugosus*, &c. The woolly *footstalks* also bear very small hooked prickles. The *leaves* are as broad as the hand, more finely and sharply crenate than those of *R.*

*elongatus*, with some irregular, shallow, obsolete, acute lobes. *Panicle* very large, lax and spreading, twice, or even thrice compound, downy, its ultimate stalks partly umbellate, but all much more long and slender than in the foregoing. The *calyx* also differs essentially in its tapering segments, downy, not silky on both sides. *Petals* small, obovate. *Fruit* black.

42. *R. pyrifolius*. Pear-leaved Bramble. Sm. Plant. Ic. t. 61. Willd. n. 23.—Leaves simple, elliptical, pointed, ferrated, smooth. Panicle corymbose, downy. Calyx partly jagged. Petals minute.—Found in Java, by Commerfon. The *branches* are slender, round, slightly zigzag, minutely hairy, armed with small recurved prickles. *Leaves* on shortish hairy *stalks*, coriaceous, three inches long, and one broad, coarsely ferrated; the ribs and veins only hairy on both sides. *Panicle* terminal, large, twice compound; its branches corymbose and downy. *Braëtas* linear, deeply jagged, deciduous. Segments of the *calyx* ovate, taper-pointed, downy on both sides; the points of two or three of them deeply divided into three or four parts, while the rest are entire. *Petals* very small, abrupt and jagged, scarcely a quarter the length of the calyx. *Fruit* of a few large grains, with wrinkled seeds.

43. *R. acuminatus*. Pointed-leaved Bramble.—Leaves simple, ovate, taper-pointed, ferrated, smooth. Panicle racemose, not downy. Petals as long as the calyx.—Found by Dr. Buchanan, in the woods at Sembu in Upper Nepaul, flowering early in July, 1802. This species is related to the last, but very distinct. The *stem* is climbing, unarmed. The *branches* are minutely prickly, but not hairy. *Leaves* four or five inches in length, scarcely coriaceous, smooth and shining on both sides, paler beneath, simply or doubly ferrated, remarkable for their long taper points. *Footstalks* channelled, prickly, as well as the midrib, hardly pubescent. *Stipulas* awl-shaped, toothed, smooth, deciduous. *Panicle* terminal, elongated, zigzag, compound, accompanied by some leaves; its ultimate branches often three-flowered. *Flower-stalks* warty, but not downy. *Braëtas* awl-shaped, simple or divided, smooth. *Calyx* warty and downy, with a short simple point to each segment. *Petals* ovate, acute, the length of the calyx, white. *Fruit* of a very bright red, larger than the calyx.

SECT. 2. *Stem herbaceous*.

44. *R. pedatus*. Pedate Bramble. Sm. Plant. Ic. t. 63. Willd. n. 24. Pursh n. 17.—Leaves pedate, of five bluntish, nearly smooth, cut and ferrated leaflets. *Flower-stalks* capillary, simple, bracteated in the middle. Calyx smoothish, partly cut, reflexed.—Gathered on the north-west coast of America, by Mr. Menzies, to whom we are obliged for specimens. This is an elegant, delicate, herbaceous plant, with creeping roots, throwing up, at intervals, short simple stems, with one or two leaves, on long, slender, channelled *footstalks*, and one, rarely two, *flower-stalks*, nearly the same length, but more slender, bearing a pair of little roundish *braëtas*, about half way up. *Stipulas* in pairs, roundish, fringed, larger than the *braëtas*. *Flowers* solitary, small. *Calyx* deeply divided; its segments oblong, some of them three-cleft. *Petals* the same length, elliptical, rather abrupt or jagged; whether white or yellow we are doubtful. If the latter, it would greatly confirm Mr. Pursh's suspicion of this plant being a species of *Dalibarda*, provided that genus should be established, a point on which we shall touch at the conclusion of this article. We know nothing of the *fruit* of our *R. pedatus*.

45. *R. saxatilis*. Stone Bramble. Linn. Sp. Pl. 708. Willd. n. 25. Ait. n. 11. Pursh n. 13? Fl. Brit.

## RUBUS.

n. 5. Engl. Bot. t. 2233. Fl. Dan. t. 134. Ger. Em. 1273.—Leaves ternate, acute, slightly downy, doubly and unequally notched. Runners creeping, herbaceous. Panicle of few flowers. Stipulas ovate.—Native of stony, rather mountainous, dry woods and thickets, in the north of Europe, chiefly confined with us to Scotland, Wales, and the most northern and hilly part of England, flowering in June. The whole herb is of a slender delicate habit, light green, slightly downy, not at all white or hoary. It spreads extensively by means of long trailing shoots, either naked or leafy, which do not blossom till their extremities have taken root. The flowering stems are solitary, erect, simple, a span high, slightly angular, leafy, hairy, besides a few occasional, very tender, horizontal prickles, often present also on the footstalks. The leaflets are in some measure rhomboid, sharply and coarsely crenate; the side ones now and then lobed at the lower margin, and very rarely two at each side. Cluster terminal, downy, of from three to five small inconspicuous flowers. Segments of the calyx lanceolate, downy, acute. Petals erect, lanceolate, bluntnish, cream-coloured or greenish. Berries of a very few large, crimson, globular grains, pleasantly acid. Seeds compressed, wrinkled.

Mr. Pursh, following Michaux, considers as a variety of this a plant found in Canada, and on the mountains from New York to Virginia, which has small black berries. The flowers are about three, on long partial stalks. Its runners accord with our *saxatilis*, but we should presume that an accurate comparison of these two plants might prove them to be distinct species.

46. *R. obovatis*. Moss American Black-berry. Michaux Boreali-Amer. v. 1. 298. Pursh n. 14.—Leaves ternate, oval, rounded, serrated, naked. Stem hispid. Clusters somewhat corymbose, of few flowers. Stipulas setaceous.—Found in swamps, among bog-mosses, on the mountains from New York to Carolina, flowering from May to July. The stem is described as rather shrubby, hispid with rigid hairs. Flower-stalks elongated. Bractees ovate. Berries with only a few large grains, black and sweet. The name, and definition of the leaves, *foliis obovatis*, are incorrect. An oval is of the same breadth at each end. We presume Michaux meant *obovate*.

47. *R. arcticus*. Dwarf Crimson Bramble. Linn. Sp. Pl. 708. Fl. Lapp. ed. 2. 170. t. 5. f. 2. Willd. n. 26. Ait. n. 13. Pursh n. 15. Fl. Brit. n. 6. Engl. Bot. t. 1585. Curt. Mag. t. 132. Fl. Dan. t. 488.—Leaves ternate, smooth, bluntly serrated. Stem mostly single-flowered, without prickles. Petals roundish, notched.—Native of Lapland, also of Labradore, and about Hudson's Bay; as well as of the isle of Mull, and the mountains of Ben-y-glo, in Scotland, flowering in May and June. The root is perennial and creeping, but without scyons. Stems unarmed, erect, leafy, from four to eight inches high, almost invariably simple and single-flowered, though sometimes from luxuriance an axillary blossom occurs at the second leaf, as drawn in Engl. Bot. Leaflets always three, ovate or rhomboid, bluntnish, with broad roundish serratures. Stipulas ovate, entire. Flower terminal, stalked, of a beautiful crimson. Calyx downy, often with six or seven segments, with which the petals agree in number. The latter are mostly emarginate, sometimes much jagged. Berry of a few large grains, amber-coloured, with a purplish tinge, about as big as a raspberry, but far superior in flavour, partaking of that fruit and the strawberry, with a luscious sweetness. Linnæus justly extols this fruit, and acknowledges his obligation to it, when fatigued with the labours of his Lapland tour. Syrup,

VOL. XXX.

jelly, and wine are made of it in Sweden, which are esteemed highly. These berries are often ripened in our gardens, provided the plant be allowed to grow with luxuriance. The seeds are scarcely perceptibly wrinkled.

48. *R. pifillatus*. Close-styled Bramble. Sm. Exot. Bot. v. 2. 53. t. 86. Ait. n. 12. Pursh n. 16. (*R. acaulis*; Michaux Boreali-Amer. v. 1. 298.)—Leaves ternate, smooth, sharply serrated. Stem single-flowered, without prickles. Petals oblong, entire. Styles clustered together.—Native of Labradore; and, according to Mr. Pursh, of the bogs of Canada, as well as the north-west coast of America, flowering in June and July. It was first cultivated in England by Mr. Dickson, in the garden of the late Rt. Hon. Charles Greville at Paddington, about the year 1802. This most resembles the *arcticus* in habit, but is of more humble stature, though by no means destitute of a stem. The leaves are more acutely serrated, and rise above the flower, which is crimson, large, and handsome, on a terminal, downy, simple stalk. Calyx with six, or more, lanceolate, narrow segments, rather downy. Petals as numerous, and twice as long, elliptic-oblong, with taper claws. Stamens club-shaped and obtuse, which is likewise the case in the *arcticus*, but in the present there is more of a capillary stalk to the anther. Germen depressed. Styles few, crowded together, looking like a simple one. We know nothing of the fruit.

49. *R. geoides*. Avens-leaved Bramble. Sm. Plant. Ic. t. 19. Willd. n. 29.—Leaves simple or ternate, obtuse, serrated, smooth; the odd leaflet very large. Stems depressed, single-flowered. Petals roundish.—Gathered by Commerçon at the Straits of Magellan. This is a humble depressed herb, with very short stems. Footstalks long, channelled, slightly hairy, each bearing two awl-shaped stipulas, a good way above the base. Leaves mostly composed of one large, heart-shaped, rounded, abrupt, unequally serrated, smooth, terminal leaflet, and a pair of, much smaller, stalked ones, which last are sometimes wanting. Flower terminal, solitary, on a thick downy stalk. Segments of the calyx oblong. Petals nearly orbicular. Fruit unknown. Commerçon observed the stamens and pistils to be always present together in each flower, in which this plant differs from *R. Dalibarda* and *Chamæmoris*, here-after described.

50. *R. trifidus*. Three-cleft Japan Bramble. Thunb. Jap. 217. Willd. n. 27.—Leaves simple, three-cleft, cut and serrated, smooth. Stem without prickles, nearly simple, erect. Flowers stalked, solitary. Calyx white and downy.—Found by Thunberg, near Quana in Japan, flowering in April. The stem is said to be rather zigzag, round, mostly simple, purple, and smooth. Leaves stalked, heart-shaped, roundish, nearly as broad as the palm of the hand; their lobes cut, and unequally serrated. Flowers from the same bud with the leaves, solitary, on a simple, rarely divided, stalk, which is like the footstalks, about a finger's length, and villous. Fruit red, eatable, agreeably flavoured. By the above description, taken from Thunberg, it should seem that there are more flowers than one on each stem; but we have seen no specimen.

51. *R. stellatus*. Starry-flowered Bramble. Sm. Plant. Ic. t. 64. Willd. n. 28. Pursh n. 18.—Leaves simple, three-lobed, rugose. Stem single-flowered. Segments of the calyx awl-shaped. Petals lanceolate.—Gathered by Mr. Menzies, near Foggy Harbour, on the north-west coast of America. The roots are perennial and creeping. Stems annual, solitary, erect, simple, leafy, downy, without prickles, about two inches high. Leaves two or three, alternate, on long downy stalks, heart-shaped, broader than they are long,

more or less deeply three-lobed, rather acute, sharply serrated, rugose, veiny, slightly hairy; paler beneath. *Stipulas* roundish, or ovate, somewhat notched. *Flower* large, terminal, solitary, much overtopped by the foliage, crimson, on a short downy stalk. *Calyx* hairy, with from five to ten long, taper segments; its base angular and ribbed. *Petals* as many, lanceolate or obovate, with taper claws. *Berry* composed of several grains. The *calyx* sometimes remains through the winter, elevated on the elongated dried *stem*, as in the plate above cited.

52. *R. Chamæmoros*. Mountain Bramble, or Cloud-berry. Linn. Sp. Pl. 708. Fl. Lapp. ed. 2. 173. t. 5. f. 1. Willd. n. 30. Ait. n. 14. Pursh n. 19. Fl. Brit. n. 7. Engl. Bot. t. 716. Lightf. Scot. 266. t. 13. f. 2. Fl. Dan. t. 1. (*Chamæmoros*; Ger. Em. 1273. *Vaccinia nubis*; *ibid.* 1420, very bad.)—Leaves simple, lobed, rugose. Stem single-flowered. Segments of the calyx ovate. Petals roundish.—Native of alpine turfy bogs in the north of Europe, frequent in Lapland, Denmark, Siberia, &c., as well as on the highest mountains of Scotland, Wales, and the north of England, flowering in June. It occurs also in Canada and New England. The roots are long and creeping, throwing up here and there solitary stems, about a span high, some bearing solitary male flowers, others female ones. Leaves shaped like those of a mallow, or currant, heart-shaped at the base, strongly veined, plaited, smooth, unequally serrated, one or two on each stem. Footstalks slightly hairy. *Stipulas* ovate, obtuse. Flower on a long downy stalk, rising above the leaves, white, elegant. *Calyx* tawny, downy, with five broad ovate segments. *Petals* about twice as long as the calyx. *Berry* of many large grains, amber-coloured, with a pleasant acid flavour resembling that of tamarinds, though rather mucilaginous. Lightfoot says, these berries are brought to table in the highlands. Linnæus speaks of them as much esteemed by the Laplanders, who preserve them through the winter, buried under the snow.

53. *R. coriaceus*. Coriaceous Peruvian Bramble. Poiret in Lamarck Dict. v. 6. 237. —Leaves simple, ovate-oblong, undivided, smooth, serrated. Stem and footstalks somewhat prickly. Flowers axillary, solitary. Segments of the calyx lanceolate. Petals roundish.—Found by Dombey in Peru. Described by Poiret, from Jussieu's herbarium. The stems are erect, nearly simple, herbaceous, reddish, compressed, very smooth, except a few small scattered prickles on their upper part. Leaves alternate, distinct, thick, and coriaceous, rather obtuse; shining on the upper side; their footstalks furnished with some small prickles. *Stipulas* oval, toothed. Flowers axillary, towards the top of the stem, on simple, thickish stalks, armed with very fine prickles. *Calyx* large, broad at the base, with five smooth, lanceolate, pointed, greenish segments. *Petals* rounded, shorter than the calyx, crenate at the extremity, appearing yellow when dry.

54. *R. Dalibarda*. Violet-leaved Dwarf Bramble. Linn. Sp. Pl. 708. Willd. n. 31. Sm. Plant. Ic. t. 20. Lamarck Illustr. t. 441. f. 3. (*Dalibarda repens*; Linn. Sp. Pl. ed. 1. 491. Poiret in Lamarck Dict. v. 6. 250. Pursh v. 1. 350. *D. violæoides*; Michaux Boreali-Amer. v. 1. 299. t. 27. Ait. v. 3. 271.)—Leaves simple, heart-shaped, undivided, crenate, hairy. Stems creeping. Stalks single-flowered. Petals ovate. Gathered by Kalm in Canada. Mr. Pursh says it is found in the shady woods and bogs of that country, and on the high mountains of New England and Pennsylvania, flowering in May and June. The herbage much resembles that of some species of violet. The root is perennial and creeping, sending forth several

depressed, creeping, round, leafy, downy stems. Leaves rounded, about an inch in diameter, finely hairy on both sides, on long, slender, hairy footstalks. *Stipulas* oblong, with several terminal awl-shaped segments. *Flower-stalks* nearly radical, about as long as the footstalks, but more slender, simple, hairy, each bearing a small white flower, not unlike a single *hepatica*, but about half the size. Segments of the calyx lanceolate, acute, downy, sometimes partly notched, nearly equal to the petals. *Stamens* capillary. *Styles* five, above half as long as the stamens. They are erroneously described "very short" in the Plant. Ic. Fruit of five, or not so many, pale, dry, ovate, obtuse grains, minutely downy, and slightly wrinkled.

The want of pulp in the fruit first induced Linnæus to separate this plant, as a genus, from *Rubus*; but he afterwards altered his opinion. His original determination has been followed by Michaux, Pursh, and Aiton. The question is difficult, but there are many different degrees of pulpiness in the several fruits of acknowledged *Rubi*, and Mr. Pursh himself describes his *cuneifolius*, see n. 15, with "hard and dry berries," though no person surely would think of placing that species any where else. Till, therefore, we can judge for ourselves, by tracing the growth of the fruit in question, and comparing it with others, we had rather follow Linnæus. Michaux says *Dalibarda* differs from *Rubus*, nearly in the same manner as *Potentilla* from *Fragaria*; but this is incorrect. These latter are distinguished by the deciduous fleshy receptacle of *Fragaria*; the others merely by more or less pulp in the berry; for *Dalibarda* has not naked seeds, or "*semina exsucca*," but possibly *bacca exsucca*, a very different matter. We shall recur to the subject again under the following species.

55. *R. fragarioides*. Strawberry-leaved Bramble. (*Dalibarda fragarioides*; Michaux Boreali-Amer. v. 1. 300. t. 28. Curt. Mag. t. 1567. Pursh v. 1. 350. Ait. v. 3. 271. Poiret in Lamarck Dict. v. 6. 250.)—Leaves ternate; leaflets all sessile, wedge-shaped, notched and serrated, fringed. Stalks radical, many-flowered. *Calyx* tubular at the base.—Native of shady beech woods in Canada, and of the Alleghany mountains, flowering in May and June. We have seen no specimen, but by the above plate, the root appears to be simple, oblong, woody and perennial. Leaves all radical, on longish slender stalks; the middle leaflet sessile like the rest, and very little larger. *Flower-stalks* longer than the leaves, somewhat paniced, bearing about five flowers, the size of the last. *Calyx* remarkably elongated, and inversely conical, at the base, with ovate, finally reflexed, segments. *Petals* ovate, said to be yellow. *Stamens* numerous; their filaments permanent, erect. Of the particular structure of the fruit we find no account. This species, with its yellow flowers, and tubular calyx, to say nothing of the herbage, is so unlike the other *Dalibarda*, that it weakens, instead of confirming, that supposed genus. We presume not to say, without actual examination, what it most resembles. Pallas, it seems, made this plant a *Dryas*. We place it here merely for further enquiry. Dr. Sims in Curtis's Magazine remarks that the calyx sometimes betrays an inclination to have intermediate segments, a very curious, though puzzling, circumstance.

56. *R. radicans*. Creeping Peruvian Bramble. Cavan. Ic. v. 5. 7. t. 413. Poiret in Lamarck Dict. v. 6. 249.—Leaves ternate; leaflets all stalked, heart-shaped, villous, serrated. Stem creeping, prickly. Stalks radical, single-flowered. *Calyx* notched. Gathered by Lewis Née, in the woods of Chili, growing at the roots, or on the rotten trunks, of trees, bearing flowers and fruit in February. The stem is quite prostrate, armed with short prickles, spread-

## RUBUS.

ing to a great extent, and fixing itself here and there, as it runs, by fibrous roots. *Leaves* several from each part where the roots are produced, forming a tuft, accompanied by a solitary, long-stalked, pale red flower, rising above the leaves, and succeeded by an ovate greenish berry, composed of numerous grains, all together the size of a currant, and said to be very agreeably flavoured. The *calyx* is reflexed when in fruit, its segments oblong, acute, with many deep notches. *Petals* roundish, obtuse.

RUBUS, in *Gardening*, contains plants of the under-shrubby and herbaceous perennial kind, of which the species cultivated are, the raspberry (*R. idæus*); the Virginian raspberry (*R. occidentalis*); the flowering raspberry (*R. odoratus*); the common bramble (*R. fruticosus*); the brittle bramble (*R. hispidus*); the dewberry bramble (*R. cæsius*); the dwarf crimson bramble (*R. arcticus*); and the mountain bramble, or cloud-berry (*R. chamæmoris*).

In the first species the varieties are, the red-fruited, the white-fruited, the twice-bearing, of which the first crop ripens in July, and the second in October, those of the latter season having seldom much flavour; the smooth raspberry, and the large Antwerp. But the sorts mostly cultivated, according to Mr. Forsyth, are, the early white, the double-bearing white, the large common white, the large red, the red Antwerp, the large white Antwerp, the smooth cane double-bearing, and the Woodward's new raspberry.

In the fourth sort there are several varieties; but that which is chiefly introduced as a garden shrub, is the double-flowered bramble.

*Method of Culture.*—In the first sort and varieties of these plants it may be effected by suckers and layers. The plants should always have a portion of ground to themselves, being planted at the distance of about six feet from row to row, and four in the rows, with the exception of the early white sort, which may be set out closer. And according to Mr. Forsyth, the ground should first be well trenched over and dunged; then, making choice of the strongest and finest plants that come out from the sides of the stools, where they have been standing for some years, or encouraging the strongest plants that come out betwixt the rows after digging, which should be done annually, they may be planted out as above. In digging the ground, it frequently happens that the roots are cut with the spade, which occasions a great number of small plants to come up; of these the strongest and finest should be selected, hoeing up all the superfluous ones. But he prefers laying down some of the strongest outside shoots in the month of March; as, by the following autumn, they will make fine roots, and may be planted out in a quarter, or piece of ground, where they are intended to remain. These will not be so liable, he thinks, to throw out suckers as those which are produced from suckers. The fresh pieces of ground should always be planted in moist weather, as the roots are very delicate, and liable to hurt, when exposed to a dry air. If, however, they are planted in dry weather, he advises that care be taken to moisten the roots with water, and cover them well with wet litter, or leaves, during the time in which they are planting out. In performing the work, a trench should be opened with a spade, along the line where the suckers or layers are to be planted, cutting off all the small fibry roots with a knife, leaving only the stronger roots; putting them into the trench, and covering them with some earth; then watering them well, and throwing the remainder of the earth over them, letting them remain till you have finished planting the piece; then, where you first began to plant, beginning to tread the ground with the foot as hard as possible along each of the trenches, and in the same direction as planted; then

with a spade levelling all the ground smooth, and running it over with a rake, taking off any stones and rubbish that may be left on the surface, so as to render it perfectly even. The plants should be watered two or three times a week, when the season is dry, till they have taken root; and it will be necessary to stake the Antwerp, and other strong growing sorts, with stout stakes, running a couple of small rails at top to tie the branches to, which will prevent their being broken by the wind, or beaten down by the rain. The early white, and smaller sorts, may be plaited together at top, tying them round with the small yellow willow, which will keep them together. Some of the early raspberries may be planted between the trees on a west aspect, to produce early fruit before those in the quarters come in. The Antwerps thrive exceedingly well against north walls or palings, and produce late crops. Such as are planted against walls or palings should be tacked to them, to keep them in their places.

And it is advised that where any of the small red and white sorts are found, they should be destroyed, planting the large red, the smooth cane double-bearing, the large red and white Antwerps, the large common white, the double-bearing white, and Woodward's new raspberry in their stead. In respect to the cutting or pruning of these plants, some, Mr. Forsyth remarks, prefer pruning them in autumn, a practice of which he by no means approves. As they bear the fruit on the wood of the preceding year, they are, he thinks, very liable to be killed by the frost in severe winters; but, by deferring the pruning till the month of February, there will be a great choice of fine wood for bearing the following summer, being careful to root out or cut down all the wood that bore fruit the preceding year, which generally dies, selecting only from five to seven of the most vigorous and strong shoots from the last year's wood to bear fruit the ensuing season. These shoots may be pruned to the length of three or four feet, according to their strength, when they are of the smooth cane double-bearing sort (which generally bears a second crop in autumn, and will, in fine seasons, continue bearing from June to November); but, if the large Antwerp, the shoots should be left five or six feet long in these prunings.

But in regard to the early white, which never grows so strong as the above sorts, it should be shortened to two feet and a half, or three feet. These should be planted in rows about three feet distant from each other, and two feet from plant to plant in the rows; always remembering to keep them clear of suckers, and to cut out the dead or last year's wood, as above; making choice of the strongest shoots for bearing wood. Great care should, however, be taken not to cut off the little spurs on the sides, which bear the fruit in this kind. Plants of this sort continue in bearing five or six years; by which time a fresh plantation should be in readiness to succeed them. The young plants often bear some fruit the first year, and come into full bearing in the second after planting. If they be suffered to remain more than five or six years on the same ground, they degenerate, and bear small fruit. And much care should be taken not to leave above eight or ten of the strongest shoots, rubbing off or pulling up all the superfluous ones; and keeping the ground well hoed and cleared of weeds between the rows, as well as in other places.

Also in the other sorts the increase may be effected by suckers, layers, cuttings, and dividing the roots, and in the two last, or herbaceous kinds, by seed. The suckers should be taken up in autumn, winter, or spring, with roots; and the strongest be planted at once into the shrubbery, and the others in nursery-rows for a year or two, or till wanted for planting.

planting. The layers should be made from the shoots, which may be done almost any time, as they readily emit roots at every joint, and become fit to plant out in the autumn following. And the cuttings should be taken off from some of the younger shoots, and divided into lengths a foot long, and planted in a shady border, either in the spring or summer season. The roots in any of the raspberry and herbaceous sorts, when increased into large bunches, may be divided or slipped into several distinct sets, and planted out separately.

The last two sorts may likewise be raised from seeds, which should be taken from the ripened fruit, and sown in a moist situation where the plants are to remain, keeping the young plants clean afterwards.

Both the first species, and all the varieties, are highly useful for their fruit; for the table, preserving, and other culinary purposes.

And most of the other sorts afford variety in the borders, clumps, and other parts of pleasure-grounds, among other hardy plants.

RUBUS, in *Ichthyology*, a name given by Joannes Cuba, Albertus, and some other writers, to the species of *ray*, usually called the *skate*, or *flaire*. See RARA (BATS and RUBUS).

RUBY, *Spinelle*, Fr., in *Minerology*, a precious stone, much valued by jewellers; but under this name a variety of minerals have not unfrequently been fold, which differ essentially in their characters. Mineralogists have also disagreed much in the classification of substances to which they have given the name of ruby. The oriental ruby is, in fact, a red variety of the sapphire, and is described under the article GEMS. It possesses greater hardness than the common ruby, and differs from it in its crystallization. The primitive form of the crystals of the common ruby is the regular octahedron, from which the secondary forms vary but little. Two crystals are sometimes united, and form a macle. The colour is red, varying from scarlet to violet and yellowish-red, and sometimes a dark red. It is infusible by the blowpipe, nor does it lose its colour by the heat. The fracture is flatly conchoidal; it has a splendid vitreous lustre. The ruby possesses a considerable degree of hardness, though its principal constituent ingredient is alumine. According to Vauquelin, it contains

Alumine	-	-	-	84.47
Magnesia	-	-	-	8.78
Chromic acid	-	-	-	6.18

To the chromic acid the common ruby owes its colouring matter. A variety of ruby has received from Häuy the name of Pleonaste; it differs from the above in containing iron in place of chromic acid, and the colours vary from a purple to blue and green. Another gem nearly resembling the ruby, the spinelle zinfisere of Häuy, called also automalite, has been classed as a sub-species of ruby, but it differs from it greatly in its constituent parts.

Automalite, like the common ruby, has the octahedral crystallization, with laminæ parallel to the faces of the crystal; its colour is a dark blueish-green, nearly opaque. The constituent parts, according to Vauquelin, are,

Alumine	-	-	-	42
Silex	-	-	-	4
Oxyd of zinc	-	-	-	28
Oxyd of iron	-	-	-	5
Sulphur	-	-	-	17

The ruby, in its most perfect state, is a gem of very great beauty and value. It is often found perfectly pure, and free from all spots or blemishes; but it is much more frequently debased by them, and greatly brought down in

its value, especially in the larger specimens. It is of very great hardness, equal to that of the sapphire, and second only to the diamond. It is various in size, but is less subject to variations in its shape than most of the other gems. It is most frequently found very small; its common size being that of the heads of the larger sort of pins; and when of this size it is very cheap; but it is also found of four, six, or ten carats; and sometimes, though but very rarely, up to twenty, thirty, or forty; nay, we have accounts of some of more than a hundred. It is never found of an angular or crystalliform shape, but always of a pebble-like figure, often roundish, sometimes oblong, and much larger at one end than the other, and in some sorts resembling a pear, and is usually more or less flattened on one side.

It is commonly so naturally bright and pure on the surface as to need no polishing: it is worn in rings, and in the crowns of princes, in its rough or native state. Its colour is red in very different degrees, from the deepest garnet colour to that of the palest red diamond, but it ever has with the red more or less of a purplish tinge. This is very plainly distinguished in the deeper coloured specimens, but in the pale ones is gradually less and less to be distinguished in proportion to their degree of colour. These are the distinguishing characters of the ruby, and by these it is easily known from the garnet, carbuncle, and other red gems.

Our jewellers are very nice, though not perfectly determinate in their distinctions; knowing this gem, in its different degrees of colour, under three names; the first is simply the *ruby*: this is the name they give to it in its most perfect and strongest coloured state.

The second is the *spinel* ruby. Under this name they know those rubies which are of a somewhat less deep and much less vivid colour than what they call the true ruby, or simply the ruby.

The third is the *balas* ruby, a name derived from Bala-keia, the name of a country where the paler rubies are principally found. Under this name they express a pale, yet a very bright ruby, with a smaller admixture of the purple tinge than in the deeper coloured one, and something resembling the colour of the damask rose. This is of a considerable value, but less than the deeper, or, as they call it, the true ruby.

Besides these, they know also two other stones under the general name rubies, calling them the *rock ruby*, and the *rubacelle*. But these are not truly of the ruby kind; the first being a very beautiful species of garnet, and having a tinge of blue with its red; and the other a hyacinth, having a manifest cast of yellow. See GEMS.

There are but two places in the East where the ruby is found; the kingdom of Pegu, and the isle of Ceylon. The mine in Pegu, where it is found in greatest plenty, is in the mountain Capelan, twelve days' journey from Siren, the residence of the king of that country. The finest rubies brought hence do not exceed three or four carats; the king reserving all the larger to himself.

In Ceylon the rubies are found in a river which descends from the mountains towards the middle of the island: some few are also found in the ground. The rubies of Ceylon are usually brighter and more beautiful than those of Pegu, but they are rare; the king of Ceylon prohibiting his people to gather them, or traffic with them. There are, as some say, rubies also found in Europe, particularly in Bohemia and Hungary, especially the former, in which is a mine of flints of divers sizes; which, upon breaking, are sometimes found to contain rubies, pretended to be as fine and hard as any of the Eastern ones.

The Greeks call the ruby *αυραυτος*, *q. d.* resisting the fire. The ancients, out of their credulity and superstition, attributed many virtues to the ruby; as that it expels poisons, cures the plague, abates luxury and incontinence, banishes sorrow, &c.

It is said the inhabitants of Pegu have the art of heightening the redness and brilliancy of rubies, by laying them in the fire, and giving them a proper degree of heat; but this seems a very erroneous account.

The ruby is formed in a stony substance, or bed, of a rose-colour, called *mother of ruby*; it has not all its colour and lustre at once, but comes to it by degrees. At first it is whitish; and, as it approaches to maturity, becomes red. Hence we have white rubies, others half-white, half-red, and others blue and red, called *sapphire rubies*. When a ruby exceeds twenty carats, it may be called a *carbuncle*; the name of an imaginary stone, of which the ancients and moderns have given us so many descriptions.

They have several modes of counterfeiting rubies; and some have carried the imitation to that length, that the most able lapidaries, till they come to try the hardness, are sometimes deceived.

Frutiere assures us very positively, that there have been rubies in France of two hundred and forty carats. Tavernier tells us he saw one in the Indies of fifty carats, which he had a mind to have bought. He adds, that the king of France has finer and larger rubies than any in the possession of the great Mogul.

The largest ruby that is known to be in the world was brought from China to prince Gargarin, governor of Siberia. It came afterwards into the hands of prince Mentchikof, and is at present one of the ornaments of the imperial crown of Russia.

**RUCCELLA, LA,** in *Geography*, a town of Sicily, in the valley of Demona; 7 miles S.W. of Cefalu.

**RUCCELLAI, BERNARDO,** in *Biography*, was born of a noble family at Florence in 1449. At the age of seventeen he married Nannina, daughter of Piero, and sister of the illustrious Lorenzo de Medici, which gave him great influence, and raised him to the highest posts in the republic. In 1480 he was appointed to the office of gonfalonier of justice; and four years afterwards he went as ambassador to the state of Genoa. In 1494 he was deputed, in the same quality, to Ferdinand, king of Naples, and afterwards to Charles VII. king of France. With his public employments he joined that cultivation of polite literature, which was frequent among the Florentines in the age of the Medici. He was intimately acquainted with Marsiglio Ficino, of whose academy he was at first one of the chief ornaments, and afterwards the firmest support. After the death of Lorenzo he was the munificent patron and protector of the Platonic academy, for the use of which he erected a sumptuous edifice, with fine gardens and groves, furnished with monuments of antiquity, serving as well for ornament as instruction. In the revolutions which followed the subversion of the Medici interest, Rucellai in-

curred the charges of ambition and inconstancy, by favouring sometimes one party and sometimes another: but, according to Mr. Roscoe, his crime, in the eyes of the Florentine historians of the succeeding century, was "an ardent love of liberty, which he preferred to the claims of kindred, and the expectations of personal aggrandizement." On the accession of Leo X. he declined the office which his countrymen would have conferred upon him of going as public orator to congratulate the pontiff, foreseeing, probably, in his elevation, the ruin of the liberties of Florence. He died in 1514, and was buried in the church of St. Maria Novella, the front of which, begun by his father, was finished by him with great magnificence. The following are the works of this patron of literature: "De Urbe Roma," which is a commentary on the description of Rome by Publio Vittore, in which he collected from all the ancient writers whatever would serve to convey a just idea of the grandeur of that capital; "De Magistratibus Romanis;" "De Bello Italico;" and "De Bello Pisano:" these have been compared with the history of Sallust. Bernardo was a poet in his own tongue; and a piece of his, entitled "Trionfo della Calunnia," was printed among the "Canti Carnafialeschi," at Florence in 1759. Roscoe's *Lorenzi de Medici*.

**RUCCELLAI, GIOVANNI,** son of the preceding, a distinguished Italian poet, was born in 1475. Improving the advantages which he naturally enjoyed under his father's roof, he became a distinguished scholar, and in 1505 the republic of Florence nominated him ambassador to the Venetian state. He took a very active part in the tumult raised by the younger citizens in the year 1512, to promote the return of the Medici to Florence. Upon the elevation of pope Leo X., who was his relation, Giovanni, in hopes of preferment, repaired to Rome, and entered into the ecclesiastical order: and in 1515 he attended Leo on his visit to Florence, on which occasion the pontiff was entertained in the Rucellai gardens with the representation of the tragedy of "Rosmonda," written by Giovanni. Leo shewed the greatest attachment to his relation, and sent him, at a very critical period, as nuncio to the court of Francis I., where he was at the death of Leo X. On that event he returned to Florence, and was sent to Rome to congratulate the new pope Adrian VI. on his accession. In this, as well as in the pontificate of Leo X., and also in the succeeding one of Clement VII., to whom he was related, he had the most sanguine hope of promotion to a cardinalate. He died in 1526, without attaining to the object of his ambition. As an author, Giovanni is known by "Le Api," The Bees, which is a didactic poem in unrhymed verse, and bears a high rank among Italian compositions in that class. His tragedy Rosmonda, already noticed, and his Orestes, are imitations, the former of the Hecuba of Euripides, the latter of the Iphigenia in Tauris. Roscoe's *Leo X.*

**RUCHENWALDE,** in *Geography*, a town of Brandenburg, on the Ucker Mark; 2 miles N.E. of Storkow.

**RUCHT,** a river of France, which runs into the Roer, near Hermbach.

**RUCK,** in *Rural Economy*, a provincial term, signifying a rude heap or bundle of any thing.

**RUCKENSTEIN,** in *Geography*, a town of the duchy of Carniola; 6 miles W. of Gurkfeld.

**RUCKERSDORF,** a town of Bavaria, in the territory of Nuremberg; 8 miles W. of Lauf.

**RUCKERSWALDE,** a town of Silesia, in the principality of Neisse; 5 miles E.S.E. of Neisse.

**RUCKINGEN**, a town of Germany, in the county of Isenburg, on the Kinzig; 5 miles N.E. of Hanau.

**RUCTATION**, **RUCTUS**, in *Medicine*, belching, an involuntary discharge of flatus from the stomach, sometimes accompanied with a portion of the solid or liquid contents of that organ.

This is usually one of the symptoms of indigestion, whether arising from a morbid condition of the stomach, or from a temporary overloading of it with too much food, or with food of an acrid, heavy, or indigestible quality, or such as is disposed to pass into fermentation. There is a natural tendency in the food, especially the vegetable portion of it, to the process of fermentation, and the consequent evolution of air; but by the influence of the gastric juice, when it is sufficient to accomplish the digestive process, this tendency is counteracted, and no air is evolved. Whence the best remedy for eructation is the improvement of the digestive power, and the avoiding of fermentative food. See **INDIGESTION**.

**RUD**, in *Ichthyology*. See **CYPRINUS Carassius**, and **CYPRINUS Erythrophthalmus**.

**RUD**, in *Rural Economy*, a term provincially signifying a sort of red ochre.

**RUDAW**, in *Geography*, a town of Prussia, in the province of Natangen; 12 miles S.W. of Lick.—Also, a town of Prussia, in the province of Samland, formerly fortified with a castle, now in ruins. Some monuments of Pagan idolatry still remain in the vicinity of Rudaw; and also a stone pillar in a field near Tranzou, erected in commemoration of a victory obtained by the knights of the Teutonic order in 1370, over Kinstud, great duke of Lithuania; 12 miles N.N.W. of Königsberg.

**RUDBECK**, **JOHN**, in *Biography*, a learned Swedish bishop, was born about the year 1581. After having obtained the elementary parts of education, he was entered at the university of Upsal, where he made such progress in the higher branches of learning, that before he had completed his twenty-third year he was appointed professor of mathematics, which, in 1610, he exchanged for his professorship of Hebrew. On the coronation of Gustavus Adolphus, he took his degree in theology, and in 1619 he was nominated to the bishopric of Vesteras. In consequence of some strong expressions which he made use of in a public oration, a violent dispute took place between him and professor Messenius, which was carried so far, that the king was obliged to interfere, and to allay the angry passions of the disputants, his majesty appointed Messenius assessor in one of the courts of justice; and in 1613 he made Rudbeck one of his own chaplains. It was owing, in a great measure, to the zeal and exertions of this prelate, that the Swedish bible, known among the learned as the Bible of Gustavus Adolphus, was published in 1618. He is also known and highly esteemed in his own country for the considerable donations which he made to the gymnasium of Vesteras, and for his aid in the improvement of other useful institutions; he died in 1646. He was author of several theological works, of which the titles are given in the General Biography. Among these was one, entitled "Privilegia quædam Doctorum, Magistrorum, Præcalaurorum, Studioforum, et Scholarum omnium, &c." This work, which excited great attention, had nearly proved the author's ruin, and was, very soon after the publication, prohibited by a decree of the senate. Upon this occasion, one of the members of the senate asserted, that a more dangerous book had scarcely ever appeared, and that it was necessary the publisher should make oath that he had not retained a single copy. It prevented the promotion of the prelate, who

would otherwise probably have been raised to the rank of archbishop.

**RUDBECK**, **OLOF**, or **OLAUS**, a man of very extensive learning and accomplishments, who if not, strictly speaking, the father of natural science in Sweden, must be reckoned among its earliest and most distinguished patrons and cultivators, was the son of John Rudbeck, bishop of Vesteras; an honest and uncourtly bishop, who spoke truth, and was never promoted. The son had a great and vigorous mind, somewhat over-luxuriant in speculation and hypothesis, but sagacious in discovery, and indefatigable in application. He was born in 1630, and educated at Upsal. Anatomy was his earliest study, and he prosecuted it with such success, that at the age of nineteen or twenty he made the important discovery of the lymphatic vessels in the liver, and, soon afterwards, of those of other parts of the body. His inaugural dissertation, in 1652, treated of the circulation of the blood. Bartholine contended with Rudbeck for the originality of the discovery of the lymphatic system, and they appear to have made it independent of each other; though Haller gives the priority, in point of time, to Rudbeck. See **BARTHOLINE**, **THOMAS**.

The university of Upsal was, at this time, advancing rapidly towards that celebrity which it has now so long maintained. Enriched with the patrimonial estates of the great Gustavus Vasa, its funds have ever been ample, and the good sense of its directors has generally led them to a right application of these resources. Rudbeck, however, having made Botany a part of his pursuits, contributed, out of his own means, to the advancement of that science. He founded a garden, which he afterwards gave to the university. He visited Holland in 1653, but returning home next year, devoted himself to the study, and, we presume, to the practice of medicine, as well as to the instruction of his pupils in anatomy. In 1658 he was appointed professor of medicine, and was fixed at Upsal for the remainder of his life. It appears that he married before the age of thirty, his son, the subject of our next article, having been born in 1660, but we have no particular account of Rudbeck's domestic history. Besides the attention which he gave to the above-mentioned pursuits, he very early addicted himself to the study of languages, history, antiquities, architecture, and music, as well as the practical art of drawing. He so far took the lead in matters of taste, that the public festivals and decorations, at the coronation of the young king Charles XI., in 1660, were put entirely under his direction.

The first botanical publication of Rudbeck seems to have been his Catalogue of the Upsal Garden, printed in 1658, the year after the establishment of that collection. To this little volume a preface in Latin and Swedish is prefixed, treating of practical horticulture, and recommending botany for its agreeableness and utility. The list is, of course, not very ample, but contains several exotic species and varieties; and when the author complains of a sharp frost on the 24th of July, we cannot but allow the protection of stoves and greenhouses to have been of the most imperious necessity, so that he could scarcely, in one year, have sufficiently provided them. An Appendix to this catalogue was printed in 1666, the garden having been, by that time, considerably enriched. The same year, 1666, not, as Linnæus has it, 1664, another similar work appeared, *Delicia Vallis Jacobæ*; a catalogue, alphabetical like the former, of a garden at Jacob's Dahl, near Stockholm, belonging to count Magnus Gabriel de la Gardie, chancellor of the kingdom of Sweden, as well as of the university of Upsal. This, though anonymous, is attributed by Linnæus

to Rudbeck. It is a little book of extreme rarity, inasmuch that Haller speaks of it by report only. A Latin poem is prefixed to the work, describing the beauty of this villa, its orangery, aviary, plantations, and fountains.

We know not at what period of his life Rudbeck first conceived the vast project of his *Campi Elysi*, in which all the plants in the world, as far as they had been discovered, were to be represented by wooden cuts, in twelve folio volumes, disposed according to Bauhin's *Pinax*. For this stupendous work he is said to have prepared ten or eleven thousand figures. The first and second volumes were already printed, when a dreadful fire reduced almost the whole town of Upsal to ashes, in the year 1702. Three copies only of the first volume escaped the fire, two of which remain in Sweden, and the third is preserved in the Sherardian library at Oxford. A few leaves of this last copy, having been deficient, are supplied in manuscript. A number of the blocks of this very volume, which consists of grasses and their allies, came into England with the Linnæan collection; and having been compared with the Oxford copy, an impression of them was given to the public in 1789, under the title of *Reliquiæ Rudbeckianæ*, the appropriate letter-press of each figure, and the Linnæan names, being subjoined. An historical preface is prefixed to this edition, as well as a dedication to Dr. John Gustavus Acrel, Professor of Medicine at Upsal, who was entrusted with the sale of the Linnæan museum and library. (See LINNÆUS.) The object of the dedication is to bear testimony to the honourable conduct of this gentleman, who, because he would not act unjustly, was accused of having received a bribe of 100 pounds, so moderate is the standard of bribery in Sweden, to betray the interest of the proprietors. Perhaps this report arose from his rejecting, for them, the offer of the same sum, from another quarter, to forfeit their engagement to the person with whom they had treated, and to whom he indignantly communicated the proposal.

The second volume of the *Campi Elysi* came from the press a little before the former; so that several copies, having got abroad, escaped the destruction of the rest. Even this, however, is a very rare book, the price of which can hardly be estimated. A copy was bought by professor Jacquin in Germany, many years ago, for about 30 guineas. This volume is in the Linnæan, Bankian, and Sherardian libraries. Containing liliaceous plants, and the Orchis tribe, it is much more splendid than the first. The figures are copied from all quarters, though several are original, and amount to about 600 in all, many of them executed with great correctness and elegance, more especially after the fine engravings of the Hortus Malabaricus. There are, of course, several repetitions of the same species, and abundance of garden varieties of Tulips, &c. The *Orchidea* are numerous, but inferior, as to the correctness of their flowers, to some other plants, a defect arising from their singularity or minuteness. The preface attributes the anticipated publication of this volume to the greater popularity and attraction of its contents; and speaks of many of the intended figures of the whole work, as to be executed from drawings made by the author himself, after original specimens, either preserved in Burser's fine Swiss herbarium, or obtained from other quarters. The author speaks of his son and nephew, each of the same name with himself, as his coadjutors, and the destined continuators of this laborious undertaking. The destruction of his materials is extremely to be regretted; for such a repository of the botanical knowledge of the time, would have been highly valuable to succeeding writers; particularly as illustrating the plants of Bauhin, so many of which are to be determined from Burser's herbarium only.

The volume in question stands alone, like the single unrivalled column of the temple of peace at Rome, a perpetual cause of regret, and a monument of irrevocable destruction.

Another great work of our author, on which, most of all perhaps, his literary celebrity depends, is entitled *Atlantica*, and ought to consist of four volumes in folio; but of these the fourth, at least, if we mistake not, is to be met with in manuscript only. The others are extremely rare, probably from the accident of the fire above-mentioned. One alone, composed of wooden cuts, is in our possession. The aim of this singular, but profoundly learned, performance, was to prove that Sweden had been the terrestrial paradise of our first parents, the *Atlantis* of Plato, and the source of all learning, ancient mythology, arts, and sciences. By a passage in Linnæus's Lapland Tour, v. 1. 19, it should seem that Rudbeck had fixed the scene of the Trojan war at a village in Gestrickland, which bears the name of Troye. The reader will no longer wonder at this, when, in one of our author's illustrative maps, he finds Helicon stationed in Lapland; the Fortunate Islands at the Orkneys; and Acheron at the Mællstrom, off the coast of Norway. The church of old Upsal, certainly a hyperborean temple of the simplest form, and the most remote antiquity, is supposed to have been a fane of Apollo. It is square, with two round-arched door-ways at each side, but no windows. Rudbeck compares it with the temple of Janus at Rome, and shews how the present cathedral of Upsal originated from the plan of a similar edifice. In these points his remarks are well worthy of attention. Those who cannot help smiling at the wildness of some of his hypotheses, must respect his learning and ingenuity, and his work is said to have excited much attention when it first appeared. At present it ranks chiefly among the baubles of mere collectors, for the sake of its rarity.

This great man did not long survive the wreck of all his hopes and labours, in the fire at Upsal. He died in 1702, aged 72, having, nine years before, resigned the Professorships of Botany and Anatomy to his son. In the frontispiece of his *Atlantica* he is represented, with rather an agreeable and sensible countenance, of a plump and sleek habit of body, with long straight hair, and the habiliments of our professors and divines in the time of the Commonwealth. He is demonstrating his peculiar opinions to a circle of ancient philosophers and poets, and Plato is lending the delighted Hesiod a pair of spectacles. Rudbeck is said to have been a man of a mild and amiable character, much esteemed for his personal qualities, as well as for his boundless erudition. We can scarcely call him the founder of Botanical Science in Sweden, because he was preceded by Chesnecopherus, under whose presidency at Upsal, in 1621, a physical dissertation on plants was published and defended by Starbeck, a native of Smoland, which evinces the deep attention this branch of philosophy had even then excited, in that famous school. The curious reader may trace, in this dissertation, many ideas, supposed to have a more modern origin. Rudbeck's Works. Haller's Bibl. Bot. and Anat. Aikin's Gen. Biog. S.

RUDBECK, OLOF, junior, son of the preceding, was born at Upsal in 1660. Having been directed by his father to his own favourite studies of medicine, botany, and antiquities, he proved worthy of such a parent, friend, and preceptor. He excelled likewise in the art of delineating natural objects, and found great advantage from this talent in his subsequent pursuits. Having travelled to Holland, he took his degree of doctor of physic, at Utrecht, in 1690, publishing on that occasion an able dissertation, *de Funda-*  
*mentali*

*mentali Plantarum Notitiâ ritè acquirendâ.* In this he asserts the necessity of arranging and distinguishing the genera of plants by their fructification alone, and prefers such leading principles as are derived from the fruit, rather than from the corolla. He rejects habit, colour, sensible qualities, time of flowering, &c. on which so much stress has been laid by superficial observers; while, on the other hand, he declines being implicitly led by the more abstruse principles of certain more philosophical botanists. Some unfortunate errors of the press occur in pages 12, 13, &c. the terms *gymno-* and *angio-spermæ* being often transposed. Rudbeck extends his remarks to nomenclature, and very much to the purpose. He had previously, at Upsal, in 1686, defended a thesis, *de Propagatione Plantarum*, which is less original, though highly creditable as a school exercise. The Upsal garden was founded immediately on his return, and enriched with seeds obtained from the collections in Holland.

On the 21st of May 1695, professor Rudbeck, junior, set out from Upsal on a tour to Lapland, accompanied by two young men, the sons of Count Gyllenborg. After his return he prepared a very ample account of his journey, having made a number of drawings for the purpose. The first part, published in 1701, in Latin and Swedish, is dedicated to king Charles XII. in a Latin, as well as Swedish, poem, and ornamented with a magnificent wood cut of the *Pedicularis Sceptrum-Carolinum*. But this volume, a thin quarto, goes no further than the province of Upland. The rest of the materials, except a collection of drawings of plants, which still exist, and perhaps rather belong to the *Campi Elysi*, seem to have perished in the fire of Upsal. Such indeed was the fate of most of the copies of the work just mentioned, entitled *Laponia illustrata*, which is therefore an extremely scarce book.

In 1720 Rudbeck, in conjunction with Benzelius, afterwards archbishop of Upsal, founded the Swedish Academy of Sciences, as it was then called, though subsequently, when other similar establishments arose at Stockholm, Lund, &c. the original one was entitled the Royal Academy of Upsal. This institution still flourishes, and has produced several volumes of Transactions in Latin. In the first, printed in 1720, is a catalogue of plants, observed by Rudbeck in Lapland, with cuts of *Lobelia Dortmanna*, and *Linnaea borealis*.

Several curious dissertations came forth, from time to time, from this learned man, which evince his deep erudition, though he betrays, like his father, somewhat of a paradoxical turn. He was particularly skilled in oriental literature, and was hence led to undertake the explanation of some of the most obscure subjects of natural history in the sacred scriptures. He contends that *Borith*, mentioned by some of the prophets, is neither an herb, nor any kind of soap, but a purple dye. He also undertook to demonstrate that the *Dudaim* were Raspberries. (See DUDAIM.) The perusal of these erudite speculations, instead of affording instruction on the subject discussed, rather leads us to the conviction, that a man who has so many tools at command, can turn and mould any subject as he pleases. The two dissertations in question appeared in 1733, in quarto. The author had previously given to the world three others, the inaugural essays of some of his pupils. These were on *Hedera*, in 1707, in 4to.; on *Mandragora*, in 1702; and on the *Rubus arcticus* of Linnæus, in 1716, both in Svo., with good cuts. His most elaborate and eccentric performance of all, perhaps, is a dissertation on the bird *Selav*, which our translation of the bible renders a quail. Some have thought it a locust, but Rudbeck will have it a flying-fish; and as Johnson maliciously says of Milton, he is never

at a loss for a reason. Abundance of profound remarks are interperfed in this treatise. Amongst other things, the affinity of the Hebrew, Chinese, and Gothic languages is discussed. The younger Rudbeck died in 1740, highly respected. He left in manuscript a sort of universal lexicon, which has never been printed. Rudbeck, jun.'s Works. Haller Bibl. Bot. Aikin's Gen. Biog. Dryand. Bibl. Banks. S.

RUDBECKIA, in *Botany*, was dedicated by Linnæus to the memory of his great countrymen, Olof Rudbeck, father and son, his predecessors in the botanical chair at Upsal. (See RUDBECK.) A genus allied to *Helianthus* was well chosen for this purpose, a Sun-flower having been the emblem, or, some say, a part of the coat of arms, of the persons commemorated.—Linn. Gen. 440. Schreb. 574. Willd. Sp. Pl. v. 3. 2246. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 130. Pursh v. 2. 573. Juss. 189. Lamarck Illustr. t. 705. Gært. t. 172.—Class and order, *Syngenesia Polygamia-frustranea*. Nat. Ord. *Compositæ oppositifolia*, Linn. *Corymbifera*, Juss.

Gen. Ch. *Common Calyx* a double row of flat, broadish, short scales, six in each row. *Cor.* compound, radiated. Florets of the conical disk numerous, perfect, tubular-funnel-shaped, five-cleft in the border; those of the radius about twelve, female, ligulate, very long, lanceolate, flat, pendulous, with two or three terminal teeth. *Stam.* in the perfect florets five, capillary, very short; anthers united into a cylindrical tube. *Pist.* in the perfect florets, germs square; style thread-shaped, the length of the partial corolla; stigma deeply divided, revolute: in the female florets, germs minute; style and stigma wanting. *Peric.* none, except the unchanged calyx. *Seeds* in the perfect florets only, solitary, oblong, each crowned with a membranous four-toothed border. *Recept.* chaffy, conical, longer than the common calyx. Scales the length of the seeds, erect, of a concave or channel-like form, deciduous.

Eff. Ch. *Receptacle* chaffy, conical. *Seed* crowned with a four-toothed border. *Calyx* of a double row of scales.

1. *R. laciniata*. Broad Jagged Rudbeckia. Linn. Sp. Pl. 1279. Willd. n. 1. Ait. n. 1. Pursh n. 12. (*Aconitum helianthemum canadense*; Cornut. Canad. 178. t. 179.)—Lower leaves pinnate; leaflets ovate, unequal at the base, toothed, somewhat three-lobed: upper ones undivided or three-cleft, ovate-oblong. Crown of the seeds four-toothed.—Native of North America. On the edges of swamps and ditches, from Canada to Virginia, flowering from August to October. *Pursh.* A hardy perennial in our gardens, where it has been known for nearly two centuries, flowering in autumn. The *stems* are from five to eight or ten feet high, erect, branched, furrowed, smooth. *Leaves* alternate, deep green, minutely rough, like a file, to the touch, pointed, variously divided. *Flowers* large, terminal, on long solitary *stalks*, erect; their radius of a full yellow; disk ovate, brown.

2. *R. columnaris*. High-crowned Rudbeckia. Pursh n. 11. Curt. Mag. t. 1601.—Stem simple, straight, with a few flowers, on long stalks, at the top. Leaves pinnatifid, cut, with linear segments. Calyx simple, five-leaved. Disk cylindrical, elongated.—Found on the banks of the Mississippi, by Mr. Frazer, who has brought it to England. The singular appearance of the *receptacle*, which is quite cylindrical, flat at the top, distinguishes this from all other known species. The *rays* are from five to eight, lax, elliptical, jagged at the end. *Leaves* narrow, roughish.

3. *R. digitata*. Narrow Jagged Rudbeckia. Mill. Dict. n. 6. Ait. n. 2. Pursh n. 13. (*Chrysanthemum americanum*

## RUDBECKIA.

*canum majus, foliis magis dissectis*; Morif. v. 3. 22. sect. 6. t. 6. f. 54.) Lower leaves pinnate; leaflets pinnatifid: upper ones deeply three-lobed, lanceolate, partly cut. Crown of the seeds crenate. Stem smooth.—Found on the mountains of Virginia and Carolina, flowering from August to October. *Pursh.* This resembles the first species, but has smaller flowers, and much narrower, rather smoother, leaves. The crown of each seed, besides having four teeth, is finely jagged or crenate.

4. *R. pinnata.* Fragrant Pinnated Rudbeckia. Venten. Hort. Cels. t. 71. Sm. Exot. Bot. v. 1. 73. t. 38. Ait. n. 3. Pursh n. 14. Michaux Boreali-Amer. v. 2. 144. (*R. digitata*; Willd. n. 2.)—Leaves pinnate, somewhat subdivided. Crown of the seed entire at the edge. Stem rough.—Native of the western parts of Carolina and Georgia, where it flowers from July to October. *Pursh.* With us it is a hardy perennial, having been introduced, from the garden at Madrid, by seeds sent to the late lady Amelia Hume. Every part of the *herbage* is minutely rough. *Flowers* large and handsome, with the scent of anise; their rays deep yellow; numerous, broad, downy, pointing downwards; disk ovate, dark purple, almost black. Ventenat mistook this for the *digitata* of Miller and Aiton.

5. *R. triloba.* Three-lobed Rudbeckia. Linn. Sp. Pl. 1280. Willd. n. 3. Ait. n. 4. Pursh n. 9. (*Chrysanthemum cannabinum virginianum hirsutum, disco nigro, petalis aureis radiato*; Pluk. Almag. 100. Phyt. t. 22. f. 2.)—Leaves spatulate; the lower ones three-lobed; the upper undivided. Stem hairy, much branched. Calyx leafy. Scales of the receptacle with prominent points.—An inhabitant of the mountains of Virginia and Carolina, flowering in August and September. *Pursh.* Stem four or five feet high, much branched and spreading, leafy, striated, rough with pale, rigid, deflexed hairs, which are more erect on the branches. *Leaves* more or less shaggy with similar hairs. *Flowers* not much above an inch in diameter, pale yellow according to Mr. Pursh, but partly orange, or tawny, in our dried specimens. Outer scales of the calyx leafy, as long as the radiant florets. *Disk* convex, hardly conical, remarkable for the projecting needle-like points of the scales, between the florets. This has long been cultivated in France as well as England, where it is biennial, though sometimes perennial in Carolina.

6. *R. subtomentosa.* Downy Rudbeckia. Pursh n. 10. (*R. triloba* β; Michaux Boreali-Amer. v. 2. 144.)—“Downy, with short pubescence. Branches erect, many-flowered. Leaves oblong-lanceolate, acute, somewhat serrated; the lower ones three-lobed. Scales of the calyx close-pressed, shorter than the rays.”—Native of mountain meadows, in Virginia and the country of the Illinois, flowering in August and September. Perennial, not near so tall as the preceding, from which it is very distinct. *Pursh.*

7. *R. Radula.* File Rudbeckia. Pursh n. 8.—“Stem hispid below; smooth, and nearly naked, above. Stalks very long, single-flowered. Leaves ovate, tapering, tuberculated, hispid. Calyx imbricated; with ovate, pointed, fringed scales.—Gathered by Bartram in Georgia. Mr. Pursh described it from the Banksian herbarium. The root is marked as biennial. We have examined no specimen.

8. *R. hirta.* Great Hairy Rudbeckia. Linn. Sp. Pl. 1280. Willd. n. 4. Ait. n. 5. Pursh n. 7. (*R. foliis lanceolato-ovatis, alternis, indivisis, petalis radii bilidis*; Mill. Ic. t. 224. f. 1. *Obeliscothea integrifolia, radio aureo, umbone atro-rubente*; Dill. Elth. 295. t. 218.)—Rough with bristly hairs. Stem slightly branched, single-flowered. Flower-stalk elongated, naked. Leaves undi-

vided, ovate, somewhat spatulate, triply ribbed, serrated. Calyx leafy. Scales of the receptacle lanceolate, hairy.—Found on the mountains from Virginia to Florida, flowering from July to September. *Pursh.* Root biennial. Herb about two feet high, rough and hairy. Flower rather large, with a dark brown disk, and long yellow rays.

9. *R. fulgida.* Small Hairy Rudbeckia. Ait. n. 6. Willd. n. 5. Pursh n. 6.—Stem hispid. Branches straight, single-flowered. Leaves oblong-lanceolate, triply ribbed, toothed, rough; contracted, and somewhat heart-shaped, at the base. Calyx leafy. Scales of the receptacle lanceolate, fringed.—In mountain meadows and woods, from Pennsylvania to Carolina, flowering from July to October. *Pursh.* Said in Hort. Kew. to have been introduced into England, by the late Messrs. Kennedy and Lee, in 1760. This differs from the last in having a perennial root; branched stem; and smaller flowers, whose rays are of a deep orange-colour, and the disk dark purple. The scales of the calyx are shorter, broader, and more ovate.

10. *R. densifolia.* Crowded-leaved Rudbeckia.—Stem rough. Branches single-flowered. Leaves opposite, stalked, elliptic-lanceolate, rough, somewhat toothed. Calyx close-pressed, not half the length of the rays.—Gathered by Commerçon, on rocks at Monte Video. The stem seems rather shrubby, branched, round, clothed with numerous leaves, and very rough with minute depressed prickles, such as cover every part of the herbage. *Leaves* about an inch and half long, more or less acute, sometimes distantly toothed; the upper ones partly scattered. *Flowers* large, on long, rough, nearly leafless stalks. Scales of the calyx ovate, rough and fringed. *Rays* numerous, broad, yellow, ascending, almost thrice as long as the calyx. *Disk* brown, or purplish.

11. *R. decumbens.* Decumbent Rudbeckia.—Stem decumbent, creeping. Leaves opposite, stalked, linear-spatulate, nearly smooth. Flower-stalks erect, solitary, angular, very long and slender, slightly hairy.—Found by Commerçon on the rocks of Monte Video. The stems are woody, creeping by means of numerous radicles, ascending at the extremity only, but producing, as they go, a dense assemblage of short leafy shoots or branches. *Leaves* very various in size and breadth, obtuse, triply ribbed, rather fleshy, very slightly and occasionally hairy, nearly entire. *Flower-stalks* terminal, solitary, simple, single-flowered, erect and straight, naked, near a span long, being ten times the length of the leaves, of equal thickness throughout. *Flowers* about an inch in diameter, yellow in the disk as well as radius. Scales of the calyx ovate, acute, close-pressed, fringed with bristles, and about half the length of the rays. We have no means of investigating the receptacle, or seed-crown, but we presume, from the habit of every part, the genus can scarcely be doubtful.

12. *R. bellidioides.* Daisy-like Rudbeckia.—Stem decumbent. Leaves opposite, stalked, ovate, rough-edged. Flower-stalks erect, solitary, very long; swelling and very downy at the top.—This likewise was gathered by Commerçon, at Monte Video. Roots creeping, with thick fleshy fibres. Stems trailing, with short leafy branches, forming a sort of tuft, much as in the foregoing, but the leafy part does not appear to take root. *Leaves* tolerably uniform, from one and half to two inches long, and half an inch wide, obtuse, triply ribbed, entire; very rough on the ribs and margin; tapering down at the base into a broad fringed footstalk. *Flower-stalks* four or five inches long, situated as in the last species, but flatter, especially towards the flower, where they are densely covered with short, rigid, close-pressed hairs. *Flowers* entirely yellow, the size of the

last. Scales of the *calyx* close-pressed, ovate, half the length of the *radius*, smooth, except a slight marginal fringe; strongly ribbed, or furrowed, at the base. The younger Linnæus, as well as Commerçon, thought this a *Rudbeckia*, nor have we sufficient doubts on the subject to spoil a flower by dissection.

13. *R. aristata*. Awn-scaled Rudbeckia. Pursh n. 5.—“Stem hispid. Branches elongated, corymbose, single-flowered. Leaves lanceolate-oblong, ferrated, hispid. Disk of the flower nearly hemispherical. Scales of the seed-crown awl-shaped, awned.”—Native of South Carolina; described by Mr. Pursh from the Banksian herbarium. The *flowers* are small, deep yellow. If there be no error in the above definition, and the *seed* be really crowned with separate awl-shaped scales, this species does not well answer to the character, or idea, of a *Rudbeckia*. The analogy of other species would lead us to suppose the scales of the *receptacle* were meant, had not the words “*paleis pappi*” been so precise.

14. *R. spatulata*. Spatulate-leaved Rudbeckia. Michaux Boreali-Amer. v. 2. 144. Willd. n. 6. Pursh n. 4.\*—“Slender, finely downy. Stems single-flowered. Leaves obovato-spatulate, entire. Calyx spreading, imbricated. Radiant florets three-toothed.”—Gathered by Michaux on the mountains of Carolina; by Bartram in Florida. It is biennial, flowering in July and August. Pursh.

15. *R. discolor*. Two-coloured Rudbeckia. Pursh n. 4.—“Branches corymbose, single-flowered. Flower-stalks naked, elongated. Leaves lanceolate, nearly entire, rough with rigid hairs. Calyx-scales ovate, acute. Petals lanceolate, entire, of two colours, as long as the calyx.”—Gathered in Florida, by Bartram. Perennial. *Flowers* small; their rays yellow above, deep orange or purple underneath. Pursh. We have not examined a specimen of either of the two last, both which Mr. Pursh described from Sir Joseph Banks's herbarium.

16. *R. levigata*. Smooth Rudbeckia. Pursh n. 3.—“Quite smooth all over. Stem polished, panicled. Branches corymbose. Stalks elongated, single-flowered. Leaves ovato-lanceolate, pointed at each end, triply ribbed, polished, nearly entire. Scales of the calyx lanceolate, the length of the rays.”—Found by Mr. Lyon, in Georgia. Perennial. The *leaves* have occasionally one or two teeth. *Rays* pale yellow, short. In Mr. Lambert's herbarium. Pursh.

16. *R. amplexifolia*. Stem-clasping Rudbeckia. Jacq. Coll. v. 5. 155. Ic. Rar. t. 592. Willd. n. 7. Ait. n. 7. Pursh n. 2. (*R. perfoliata*; Cavan. Ic. v. 3. t. 252.)—Leaves elliptic-oblong, heart-shaped at the base, naked, rough-edged; the lower ones ferrated. Stem smooth, striated. Disk nearly cylindrical.—Native of Lower Louisiana, on the banks of the Mississippi, flowering in July and August. We had a specimen in 1793, from the garden of Mr. Salisbury, who received seeds the preceding year, said to have been collected by Michaux, in New Orleans. The *root* is annual. *Stem* erect, branched, round, leafy, about two feet high. *Leaves* of a pale glaucous green, acute, alternate, reticulated with veins, very smooth, except at the edge, which is beset with minute close prickles. *Flowers* solitary, at the summit of each branch, erect, with broad, dependent, deep yellow *rays*, each terminating in two or three blunt teeth; and an elongated, obtuse, dark green or blackish *disk*.

17. *R. purpurea*. Purple Rudbeckia. Linn. Sp. Pl. 1280. Willd. n. 8. Ait. n. 8. Pursh n. 1. Curt. Mag. t. 2. Chrysanthemum americanum, doronicifolium, &c.; Pluk. Phyt. t. 21. f. 1. Catesb. Carol. v. 2. t. 59.)—

Leaves rough, ovate, tapering at the base, undivided, toothed; the upper ones lanceolate, entire. Rays very long, pendulous, cloven.—On the mountains from Virginia to Florida, flowering from August to October. Pursh. This elegant and hardy perennial plant has been more than a century in our gardens. It thrives best in a rich moist soil, and is propagated by parting the roots. The *stems* are three or four feet high, erect, round, striated, smooth, mostly purplish. *Leaves* triply ribbed, near a span long, rough and harsh to the touch; the lower ones on long stalks. *Flowers* terminal, solitary, very large, and of a beautiful, as well as singular, aspect; the *disk* obtusely conical, brown, beset with the long, prominent, rigid, spinous scales of the *receptacle*; *radius* of numerous, linear-lanceolate, pink or light crimson *florets*, each three inches long, pendulous, acute and cloven at the extremity. Mr. Curtis observes that the *seeds* are rarely perfected here, nor do the *roots* increase very fast. Linnæus has strangely erred, in referring to this species, Miller's yellow-flowered figure, which belongs to *R. hirta*; see n. 8.

*R. angustifolia*, Linn. Sp. Pl. 1281. Willd. n. 9, proves the very same plant with *Helianthus angustifolius* of the same authors.

*R. oppositifolia*, Linn. Sp. Pl. 1280, is, according to Mr. Pursh, the same as *Helianthus lewis*, Linn. Sp. Pl. 1278, and *Silphium solidaginoides*, ibid. 1302. Perfoon has established it as a new genus, by the name of *Helioopsis lewis*, and he is followed by Pursh, p. 563. The *leaves* do not answer to the specific name, being rough with bristly warts.

*R. alata*, Jacq. Ic. Rar. t. 593, is *Helium quadridentatum*, Willd. Sp. Pl. v. 3. 2121. Pursh 560. See HELENIUM.

RUDBECKIA, in *Gardening*, contains plants of the herbaceous, biennial, and perennial kinds, of which the species cultivated are, the broad jagged-leaved rudbeckia (*R. laciniata*); the narrow jagged-leaved rudbeckia (*R. digitata*); the hairy rudbeckia (*R. hirta*); the purple rudbeckia (*R. purpurea*); the narrow simple-leaved rudbeckia (*R. angustifolia*); and the three-lobed rudbeckia (*R. triloba*).

*Method of Culture*.—All the sorts of these plants may be increased by off-sets, parting the roots and seeds. The off-sets in the perennial sorts should be taken off, and planted out in the early autumn: when the stems decay, the roots may also be divided, and planted out at the same time, or in the early spring months. And as these plants are often liable to go off soon, some should be frequently raised to keep up the stock; and others have a tendency to become biennial, and decay without increasing the root: they should have the flower-stems cut down in the early summer, to encourage the growth of the root off-sets, for slipping in the following autumn.

However, all the sorts may be raised from seed, and the biennial sorts must always be raised annually in that way; likewise such of the perennial kind as are biennially inclined, sowing the seeds in April, in a border of light earth, raking them in; and when the plants are two or three inches high, pricking them out in nursery-rows till autumn, then planting them out where they are to remain. They should have a light dry soil, and rather warm situation. They all afford much ornament and variety in the borders and clumps, among other flowering plants.

RUDDER, in *Navigation*, a piece of timber turning on hinges in the stern of a ship; and which opposing sometimes one side to the water, and sometimes another, turns or directs the vessel this way or that.

The rudder becomes gradually broader, in proportion to its

## RUDDER.

its distance from the top, or to its depth under water. The back, or inner part of it, which joins to the stern-post, is diminished into the form of a wedge through its whole length, so as that the rudder may be the more easily turned from one side to the other, where it makes an obtuse angle with the keel. The hinges, which are bolted round the stern-post to the after-extremity of the ship, are called *googings*, and are furnished with a large hole on the after-part of the stern-post. The other parts of the hinges, which are bolted to the back of the rudder, are called *pintles*, being strong cylindrical pins, which enter into the googings, and rest upon them. The length and thickness of the rudder are nearly equal to those of the stern-post. The rudder is turned upon its hinges, by means of a long bar of timber, called the *tiller*, which enters nearly in an horizontal direction into the ship, passing under the upper or middle deck transom; and its operation is directed by the tiller-rope, which in large vessels is wound about a wheel. (See *TILLER*.) The power of the rudder is reducible to that of the lever, and the oblique action of the water upon it is to be determined by the resolution of forces.

In order to explain the action of the rudder on the ship, it should be considered that if, instead of leaving the rudder exactly in a right line with the keel, so as to be a kind of prolongation of it, it be turned to one side or the other, as *BD* (*Plate IV. Navigation, fig. 4.*), it receives an immediate impulse from the water, which glides along the ship's bottom, in running aft from *A* to *B*; and this fluid impels it towards the opposite side, while it continues in that situation, so that the stern, to which the rudder is confined, receives the same movement; and the ship receiving an impulse sideways, her stern turns accordingly from *B* to *b*, on any point whatever *C*, while her head passes from *A* to *a*. It must be observed, that the water strikes the rudder obliquely, and only with that part of its motion which acts according to the sine of incidence, in impelling it in the direction *NP*, with a force which depends not only on the rapidity of sailing, but also on the greatness of the sine of incidence; a force which is consequently in the compound ratio of the square of the greater or less velocity of the ship's motion, and of the square of the larger or smaller sine of incidence, which depends upon various circumstances. So that, if the vessel runs three or four times more swiftly, the absolute shock of the water upon the rudder will be nine or sixteen times stronger under the same angle of incidence, and will be augmented in a greater proportion, if the sine of incidence be increased. This impulsion, or, what is the same, the power of the helm, is always very feeble, when it is compared with the whole weight of the vessel; but it acts with a very long arm of a lever, which occasions it to work very advantageously in turning the ship; for the helm is fixed at a very great distance from the centre of gravity *G*, as well as from the point *C*, upon which the ship is supposed to turn, with respect to the point of percussion *B*; and if the direction *PN* of the impression of the water upon the rudder be prolonged, it is evident that it will pass perpendicularly at the point *R*, widely distant from the centre of gravity *G*; therefore the absolute effort of the water is very powerful. It is not therefore surprising, that this machine impresses the ship with a considerable circular movement, by forcing the stern from *B* to *b*, and the head from *A* to *a*, and even much farther, when the velocity of the ship is preserved; because the effect of the helm always keeps pace with the rapidity of the ship's way.

Amongst all the obliquities which may be given to the rudder, there is one situation which is more favourable than

any of the others, to make it produce with more rapidity the effect of turning the ship, in order to change her course. To be convinced of this, we have only to consider that, if the obtuse angle *ABD* (*fig. 4.*) were to be lessened, the impulse of the water on the rudder would augment, at the same time that it would more oppose the sailing of the ship, since the angle of incidence would be more open, and would present a greater surface to the shock of the water, by opposing its passage more perpendicularly: but then the direction *NP* of the effort of the helm upon the ship would pass at a smaller distance from the centre of gravity *G* towards *R*, and would less approach the perpendicular *NL*; according to which, it is absolutely necessary that the power should act with greater effect to turn the ship. Therefore, it is evident, that, if the obtuse angle *ABD* were too much lessened, the greater shock of the water could not counterbalance the loss occasioned by the distance between the direction *NP* and *NL*, or by the great obliquity which would be given to the same direction *NP* of the absolute effort of the helm with the keel *AB*. If, on the other hand, the angle *ABD* were made more obtuse, the direction *NP* of the effort of the rudder would become more advantageous to turn the ship, since it would approach more the perpendicular *NL*, and since the prolongation of *NP* would augment *GR*, by passing at a greater distance from the centre of gravity *G*. But the rudder would then be struck too obliquely; for the angle of incidence would be more acute; so that it would only present a small part of its breadth to the shock of the water, and would of course receive but a faint impulsion. All this proves that the greatest distance *GR* from the centre of gravity *G* will not counterbalance the too great obliquity of the shock of the water. Whence it must be concluded, that when the water strikes the rudder too obliquely, or too perpendicularly, a great deal of the impulsion, or of the effect it should produce, is lost. Therefore, between these two extremes, there is a middle position, which must be the most favourable.

The diagonal *NP* of the rectangle *IL* (*fig. 4.*) represents the absolute direction of the effort of the water upon the rudder: *NI* expresses the portion of this effort which opposes the ship's head-way, or which forces her a-stern in the direction of the keel. It is easy to perceive that this portion *NI* of the whole power of the helm contributes little to turn the vessel; for, if *IN* were prolonged, it would be seen that its direction passes at a very small distance *GV* from the centre of gravity *G*, and that the arm of the lever *BN = GV*, to which the force is as it were affixed, is at most equal only to one half of the breadth of the rudder. But it is not so with respect to the relative force *NL*, which acts perpendicularly to the keel. If the first force, *NI*, is almost useless, and even hurtful, by retarding the velocity; the second, *NL*, is capable of a very great effect, since it is applied at a great distance from the centre of gravity *G* of the ship, and acts on the arm of a lever *GE*, which is very long. Thus it appears, that, between the two effects *NL* and *NI*, which result from the absolute effort *NP*, there is one which is always opposing the ship's head-way, contributing but little, therefore, to the motion of her turning; whilst the other alone produces that movement of evolution, without retarding her velocity.

As to the most advantageous angle made by the helm, with the line prolonged from the keel, geometers have fixed it at  $54^{\circ} 44'$  (See *DYNAMICS, MECHANICS, and WINDMILL.*) But it has been said, that, in determining

this angle, they have presumed that the ship is as narrow at her floating line, or at the line described by the surface of the water round her bottom, as at the keel; whereas all vessels increase in breadth from the keel upward to the extreme breadth, where the floating line, or the highest water-line, is terminated; and, therefore, the angle above stated is too large. For the rudder is impressed by the water, at the height of the floating line, more directly than at the keel, because the fluid exactly follows the horizontal outlines of the bottom; so that a particular position of the helm might be supposed necessary for each different incidence which it encounters from the keel upwards. But as a middle position may be taken between all these points, it will be sufficient to consider the angle formed by the sides of the ship, and her axis, or the middle line of her length, at the surface of the water, in order to determine afterwards the mean point, and the mean angle of incidence. The angle  $54^{\circ} 44'$ , it is said, is too open, and very unfavourable to the ship's head-way, because the water acts upon the rudder there with too great a sine of incidence, as being equal to that of the angle which it makes with the line prolonged from the keel below; but above, the shock of the water is almost perpendicular to the rudder, because of the breadth of the bottom, or that of the ship's sides. If then the rudder is only opposed to the fluid, by making an angle of  $45^{\circ}$ , or  $45^{\circ} 1'$ , with the line prolonged from the keel, the impression, by becoming weaker, will be less opposed to the ship's head-way, and the direction NP (*fig. 4.*) of the absolute effort of the water upon the rudder, approaching nearer to the lateral perpendicular NL, will be placed more advantageously, since the prolongation of the absolute effort passes at a greater distance GR from the centre of gravity of the ship. To which it is added, that experience daily testifies, that a ship steers well, when the rudder makes the angle DBE no more than  $35^{\circ}$ . If this angle be made  $45^{\circ}$ , and the absolute effort NP be decomposed, we shall have NI equal to the other side NL of the same square; so that the part of the whole power which opposes the head-way of the ship would be only equal to that which produces the movement of rotation; instead of which, if DBE were  $54^{\circ} 44'$ , NI would become much greater than NL, in proportion to the sines of the angles which are opposed to them in the triangles PIN or PLN, and the ship would lose much more of her velocity than in the first situation of the rudder, which is thought to be best adapted to vessels in general, subject, however, to occasional alteration, as they shall make an angle more or less open with their sides a-stern. Hence it has been concluded, as a general position, that the most advantageous angle will always be found between  $35^{\circ}$  and  $45^{\circ}$ . From Bouguer's treatise (*ubi infra*), it appears, that, in most ships, the angle of the rudder with the prolonged line of the keel should be  $46^{\circ} 40'$ . L. Euler recommends an obliquity somewhat less than  $54^{\circ} 44'$ , for the greatest action of the rudder; and establishes this rule, that an obliquity of about  $48^{\circ}$  will, in general, produce the best effort.

Those who duly consider the action of the *helm* and *tiller* (for an account of which, see those articles) will easily conceive, that the greater the ship's velocity is, the more powerful is the action of the rudder, since it acts against the water with a force which increases as the square of the velocity of the fluid, whether the ship has head-way, or stern-way; observing always, that in these two circumstances the effects are contrary; for, if the ship goes a-stern, the rudder will be struck from I to N (*fig. 4.*); and, instead of being pushed from N to P, it will be so from N to R; so that the

stern being moved in the same direction, the head will take a contrary one, and move towards the same side as the tiller BF.

It should be observed, in the use of the rudder, that there is one part of its effort which impedes the ship's sailing, when it is struck by the water which runs rapidly along the ship's bottom. If it makes an angle of  $45^{\circ}$  with the keel prolonged, it receives only half the impulsion it would, if acted upon perpendicularly; because the absolute impulse diminishes from two causes. The surface which opposes the shock of the water is reduced to a less extent than it was at first, and the angle of incidence diminishes likewise; so that by this, the impulse has diminished one half. Considering next the impulsion NP, which remains (*fig. 4.*), it will appear that there is only one part NI which is opposed to the sailing, and which is less than NP, in the proportion as the sine total is to the sine of  $45^{\circ}$ , the measure of the angle of incidence VNB equal to NPI; for the angle VNL is right, as well as the angle PNB; so that, if you take away the common angle LNB, the two angles PNL and VNB will remain equal between themselves; but, as the angle IPN is equal to its alternate angle PNL, it follows that IPN is always equal to VNB, whether the angle made by the rudder be more or less open with the keel prolonged. So that, if the surface of the rudder which receives the shock be 80 feet square superficies, it will first be reduced, by its being exposed to the course of the fluid, to an effort of 40 feet surface, then to 28 or 29; because, in the first place, there is only one part of the velocity of the water which contributes to the shock, and that is proportional to the relation of the square of the sine total to that of the sine of incidence; and, secondly, because out of the absolute impulse NP, which results from this last oblique shock, there is only a part NI which opposes the velocity of the ship proportional to the absolute force NP, in the same relation as there is between the sine total and the sine of incidence; that is to say, that when the rudder makes, in the largest ships, an angle of  $45^{\circ}$ , it impedes the ship's rapidity of sailing, in the direction of the keel, with an effort NI, equivalent to the impulsion which a surface of 28 or 29 feet square might receive, if it were exposed perpendicularly to the shock of the water. So that, if the ship sails 12 knots an hour, or 19 feet a second, the effort of the rudder NI, which opposes the ship's way, will be 12,499 or 12,945 pounds; salt water weighing  $\frac{1}{15}$ th more than fresh.

It follows, from all that has been said of the rudder, that it ought to be employed as little as possible; that is to say, the ship and her sails ought to be so disposed, that the smallest motion of this machine may bring her to her course, if she deviates from it, or make her perform any evolution which may be thought proper.

The ingenious writer of the article *Seaman'ship* in the Enc. Brit. suggests, that the theory of M. Bouguer and some other French mathematicians is founded on principles that are erroneous. They allume, as we have above supposed, that the impulse of a fluid is in the proportion of the square of the sine of the angle of incidence; and also that its action on any small portion, such as a square foot of the sails or hull, is the same as if that portion were detached from the rest, and were exposed, single and alone, to the wind or water in the same angle. Both these principles, it is affirmed, are erroneous; and the error is very considerable in cases which most frequently occur in practice, that is, in the small angles of inclination. The error of this theory, especially in cases of great obliquity, may be seen in the

following

following table: in which the first column exhibits the angle of incidence; the second, the impulsions really observed; the third, the impulsives, if they had followed the duplicate ratio of the sines; and the fourth, the impulsives according to the simple ratio of the sines.

Angle of Incidence.	Impulsions observed.	Impulses in dupl. Ratio of Sines.	Impulses in simple Ratio of Sines.
90	1000	1000	1000
84	989	989	995
78	958	957	978
72	908	905	951
66	845	835	914
60	771	750	866
54	693	655	809
48	615	552	743
42	543	448	669
36	480	346	587
30	440	250	500
24	424	165	407
18	414	96	309
12	406	43	208
6	400	11	105

The error in the second principle of the theory is still greater, and the action on one part of the sail or hull is so greatly modified by its action on another adjoining part, that a stay-sail is often seen hanging like a loose rag, although there is nothing between it and the wind; and this merely because a great sail in its neighbourhood sends off a lateral stream of wind, which completely hinders the wind from getting at it. Till the theory of the action of fluids be established, therefore, we cannot tell what are the forces which are acting on every point of the sail and hull: therefore we cannot tell either the mean intensity or direction of the whole force which acts on any particular sail, nor the intensity and mean direction of the resistance to the hull; circumstances absolutely necessary for enabling us to say what will be their energy in producing a rotation round any particular axis. In like manner, we cannot, by such a computation, find the spontaneous axis of conversion (see ROTATION), or the velocity of such conversion. In short, we cannot pronounce with tolerable confidence *à priori* what will be the motions in any case, or what dispositions of the sails will produce the movement we wish to perform. The experienced seaman learns by habit the general effects of every disposition of the sails; and though his knowledge is far from being accurate, it seldom leads him into any very blundering operation. Perhaps he seldom makes the best adjustment possible, but seldom still does he deviate very far from it; and in the most general and important problems, such as working to windward, the result of much experience and many corrections has settled a trim of the sails, which is certainly not far from truth, but (it must be acknowledged) deviates widely and uniformly from the theories of the mathematician's closet. The honest tar, therefore, must be indulged in his joke on the useless labours of the mathematician, who can neither hand, reef, nor steer.

Bouguer *Traité de la Manœuvre des Vaisseaux*. Falconer's *Marine Dict.* art. *Helm*; and Euler's *Complete Theory of the Construction and Properties of Vessels*, translated by Mr. Watson, 1776, book ii. chap. vii. viii. ix.

A narrow rudder is best for a ship's sailing, provided she can feel it, that is, be guided and turned by it; for a broad rudder will hold much water when the helm is put over to

any side; but if a ship have a fat quarter, so that the water cannot come quick and strong to her rudder, she will require a broad rudder.

The utmost part of the rudder is called the *rake* of the rudder.

Large canal boats have *clasp-rudders*, about half their length being moveable on hinges, so as to fold and shorten them before the entering of a lock.

*RUDDER-Coats*, are coverings made of well-tarred canvas, to prevent the water from running in at the rudder-hole.

*RUDDER-Irons*, in a *Ship*, are the cheeks of that iron of which the pintle is part, which is fastened and nailed down about the rake of the rudder.

*RUDDER-Pendants*. See *PENDANTS*.

*RUDDER-Rope*. See *ROPE*.

*RUDDER-Tackle*. See *TACKLE*.

**RUDDIMAN**, THOMAS, in *Biography*, was born in the parish of Boyndie, Banffshire, in the year 1674, where he received the first rudiments of his education, and in 1690 he was sent to King's college, Aberdeen, where he obtained a burfary. He took the degree of M. A. in 1694, and in the following year he was elected master of the public school of Laurence-Kish. In 1700 he removed to Edinburgh, and two years afterwards he was appointed librarian to the faculty of advocates. In 1709 he published Johnson's metrical paraphrase of Solomon's Song, and soon after he added a very accurate glossary to the folio edition of Gawin Douglas's translation of the Eneid. His situation at the advocates' library was so favourable to his literary pursuits, that he declined an invitation from the magistrates of Dundee, to the office of rector of the grammar-school in that town. In 1714 he published his "Rudiments of the Latin Tongue," which became a very popular book in Scotland, and was used in many schools in South Britain. In 1725 he edited "Buchanan's Opera omnia," in two vols. folio, to which he added notes critical and explanatory. About the same time he commenced the business of printer, in conjunction with his brother Walter. In 1720 he published the first part of his "Grammaticæ Latinæ Institutiones," which was very soon followed by his "Grammatical Exercises." Of the various works which issued from the press of the Ruddimans, the most important were the "Greek Testament," and an edition of the works of Livy: the last is reckoned an extremely correct edition. He also edited Anderson's "Diplomata et Numismata Scotiae," to which he prefixed a learned preface. He exhibited great critical acumen in his vindication of "Buchanan's Version of the Psalms," against the objections of Mr. Mann, and by "Critical Observations on Burman's Commentary on Lucan's Pharsalia." Some treatises on disputed points of Scottish history involved him in controversies, in which he met with much abuse, but he did not lose his own temper, though he was a warm advocate for the national independence of Scotland, and much attached to the house of Stuart. At an advanced age his eye-sight began to fail him, and he resigned the office of librarian to the faculty of advocates in 1752. He died in January 1757, at the age of 83. Chalmer's *Life of Ruddiman*.

**RUDDOCK**, in *Ornithology*, an English name for the *rubecula*, more commonly known by the name of the *red-breast*, or *robin-red-breast*.

**RUDELSHOFFEN**, in *Geography*, a town of Germany, in the margraviate of Anspach; four miles E. of Uffenheim.

**RUDELSTADT**, a town of Silesia, in the principality of Schweidnitz; 16 miles W. of Schweidnitz. N. lat. 50° 42'. E. long. 15° 59'.

RUDEN, a small island in the Baltic, near the coast of Pomerania, amidst shoals and sand-banks, which render it probable that it was formerly much larger; and this conjecture is confirmed by another circumstance, *viz.* that in the year 1264 it had two church-villages, called "Ruden" and "Carven." On this island is a castle; and between it and the little island of Die is a sand eight miles long and two broad. N. lat. 53° 40'. E. long. 13° 48'.

RUDEN, or *Tydal*, a mountain which separates the province of Jamptland in Sweden, from the province of Drontheim in Norway.

RUDENHAUSEN, a town of Germany, in the county of Castell; 28 miles W.S.W. of Bamberg.

RUDENTURE, in *Architecture*, the figure of a rope, or staff, sometimes plain, sometimes carved; with which a third part of the fluting of columns is frequently filled up.

It is thus called from the Latins *rudens*, *cable*, whence some call it a cabling; and the columns, whose flutings are thus filled, they call *rudented*, or *cable columns*.

There are also rudentures in relieve, laid on the naked of pilasters, not fluted; an instance of which we have in the church of St. Sapienza at Rome.

RUDERATION, RUDERATIO, in *Building*, a term used by Vitruvius for the laying a pavement with pebbles, or little stones.

To perform the ruderation, it is necessary the ground be first well beaten, to make it firm, and to prevent its cracking. Then a stratum of little stones is laid, to be afterwards bound together with mortar, made of lime and sand, called by Vitruvius *statumen*.

If the sand be new, its proportion to the lime may be as three to one; but if dug out of old pavements, or walls, as five to two.

RUDERATION, Daviler observes, is used by Vitruvius, lib. vii. cap. 1. for the coarsest and most artless kind of masonry; where a wall is, as it were, cobbled up.

RUDGELEY, in *Geography*, a market-town in the parish of Rudgeley, east division of the hundred of Cuttlestone, county of Stafford, England, is situated on the south bank of the river Trent, at the distance of 9½ miles E.S.E. from the town of Stafford, and 131½ miles N.W. by N. from London. It has been long celebrated on account of its great annual fairs for horses, particularly those of the coach breed. The market day is Tuesday, weekly; and the fairs are held on the 6th of June and 20th of October. The church, which stands on the north side of the town, is not remarkable as a building, but it contains several handsome monuments to the memory of the Chetwynd and Weston families. The living is a vicarage in the patronage of the dean and chapter of Lichfield.

The ancient owners of Rudgeley were of the same name with the town, and seem to have continued in possession till the reign of Henry VI. In the time of Edward III. some of the family were sheriffs of the county; and one was a knight of the shire during the same period. Erdeswick states that this manor subsequently belonged to the bishops of Lichfield, and was alienated by bishop Sampson to the crown in 1547.

On the opposite bank of the Trent from Rudgeley, are several villages named Ridwane, and distinguished from each other by the adjunct Hamfall, Pipe, and Mavefyn or Malveyfyn. Of these, the last is the most important; and its church is interesting to the antiquary, on account of the numerous ancient monuments it contains in memory of the Mavefyns, lords of the manor, several of whom were military characters of considerable eminence. Hugo Mavefyn, the founder of the church, is represented by a stone figure

in chain armour, armed and equipped for battle, lying under a pointed arch in the north wall of the church. Adjoining, under another similar arch, is the recumbent figure of sir Henry Mavefyn, a knight crusader. Like his predecessor, he appears completely armed, and dressed in chain mail; but differs from him in having his legs crossed, and his shield charged with cross bars. The other tombs are altar-shaped, and are situated in the middle of the church. That of sir Robert Mavefyn recalls to memory a melancholy story, thus related by Mr. Pennant: "In the beginning of the reign of the usurping Henry, when the kingdom was divided against itself, two neighbouring knights, sir Robert Mavefyn, and sir William Handfacre, of Handfacre, took arms in support of different parties: the first to assert the cause of Bolingbroke; the last that of the deposed Richard. They assembled their vassals, and began their march to join the armies, then about to commence battle near Shrewsbury. The two neighbours, with their respective followers, unfortunately met not far from the seats. Actuated by violent party rage a skirmish ensued: sir William was slain on the spot. What a picture is this of the misery of civil dissention? What a tale the following of the sudden vicissitude of hatred to love, between contending families? Margaret, one of the daughters, and coheirs, of sir Robert Mavefyn, gave her hand to sir William, son of the knight slain by her father, and with her person and fortune compensated the injury done by her house to that of Handfacre."

About two miles to the north-west of Rudgeley, close to the river Trent, stand the church and village of Colwich. The first is very ancient, and is prebendal to the cathedral of Lichfield. Here are several tombs in memory of the Ansons, ancestors of the present lord Anson; also of the Wolfelys, proprietors of Wolfely park, which is situated on the southern bank of the Trent, and displays much fine and picturesque scenery. Cannock chace, which extends to the southward, and contains an area of nearly forty miles square, was formerly a forest, but has been long stripped of its foliage, and is now a heathy waste, only remarkable for the extensive prospects it affords, and for its richness in coal-mines. On its eastern boundary is Beaufert park, the princely seat of the earl of Uxbridge, which is placed on the declivity of a lofty sloping eminence, sheltered on all sides by "beautiful rising grounds, embosomed with trees, and commanding in front, over the tops of far subjacent woods, a most extensive and diversified view; so that it well vindicates the propriety of its name." The house was erected in the reign of queen Elizabeth, by Thomas, second lord Paget. It is a handsome structure of stone, built in the form of a half H, and has been of late years greatly improved by its noble owner. On the summit of the hill on which it is situated, may be seen the remains of an ancient British post, called Castle-hill. It is formed by two deep ditches, and an immense rampart, and has one entrance on the east and another on the west. Near the base of the hill on its east side, stands the village of Fairwell, the church of which was formerly attached to a priory of Benedictine nuns. Originally it was the property of canons regular, or hermits, but at the request of several of the brethren it was bestowed on the nunnery in 1140, by Roger de Clinton, bishop of Lichfield, who further endowed it with considerable possessions. King Henry II. was likewise a great benefactor to this society. Pennant's Journey from Chester to London, 4to. Lond. 1782. The History and Antiquities of Staffordshire, &c. by the Rev. Stebbing Shaw, B. D. F. S. A. vol. i. fol. Lond. 1798.

RUDHAN, a town of Persia, in the province of Kerman; 60 miles N.W. of Sirjan.

**RUDIARIUS**, in *Antiquity*, a veteran gladiator, who had got a discharge from the service.

He was thus called, because, as a mark of dismissal, a rod was put into his hands, called *rudis*; which see.

The *rudarii* were also called *spectatores*.

**RUDIMENTS**, **RUDIMENTA**, the first principles, or grounds, of any art or science, called also the elements thereof.

**RUDIS**, a knotty, rugged stick, which the prætor, among the Romans, gave the gladiators, as a mark of their freedom and dismissal.

The *rudis* seems to have been bestowed both on slaves and freedmen; with this difference, that it procured for the former no more than a discharge from any farther performance in public, upon which they commonly turned *lanista*, spending their time in training up young fencers; but the latter, who had hired themselves out for these shows, were restored to a full enjoyment of their liberty. Kennet, Rom. Ant. p. 280.

Hence the Latin phrase, *rude donare*, to make a gladiator free, to discharge him from fighting any more. They were hence called *rudarii*, and had a custom of hanging up their arms in the temple of Hercules, the patron of their profession, and were never called out again without their consent.

**RUDISHEIM**, in *Geography*, a town of Germany, in the Rhingau, celebrated for its wine; 19 miles W. of Mentz.

**RUDKIOPING**, a sea-port town of Denmark, on the W. coast of the island of Langeland, and the only town in the island; the inhabitants carry on a considerable trade in corn and provisions. N. lat.  $54^{\circ} 37'$ . E. long.  $10^{\circ} 45'$ .

**RUDMAS DAY**, in our *Old Writers*, the feast of the Holy Cross. There are two of those feasts, one on the third of May, being the Invention of the Cross; and the other the fourteenth of September, called *Holy Rood-day*, and is the Exaltation of the Cross.

The word is compounded of the Saxon *rode*, i. e. *crux*, and *mas*-day, i. e. *feast-day*.

**RUDNA**, in *Geography*, a town of Hungary; 12 miles N.N.W. of Kemnitz.

**RUDNIK**, a town of Servia; 40 miles N.N.E. of Jenibasar.

**RUDNIKI**, a town of Lithuania, in the palatinate of Wilna; 15 miles S.S.W. of Wilna.

**RUDNIKZA**, a town of European Turkey, in Servia; 46 miles S. of Belgrade.

**RUDOLFSOWITZ**, a town of Silesia, in the lordship of Pleßz, on the Biela; three miles S.E. of Pleßz.

**RUDOLFSTEIN**, a town of Germany, in the principality of Culmbach; five miles N.W. of Hof.

**RUDOLFWERTH**, **NEUSTADTEIN**, or *Novomesto*, a town of Austria, in the duchy of Carniola, situated on the Gurk, and founded in the year 1365, by the Austrian archduke Rodolph IV. privileged, and called after his own name. It has a provostship or collegiate church, erected in the year 1509, four other churches, and two convents. By incursions of the Turks in the fifteenth and sixteenth centuries, successive fires, and the plague, this town has been very much reduced from its former flourishing condition;  $\frac{1}{4}$  miles S.S.W. of Pettau. N. lat.  $45^{\circ} 52'$ . E. long.  $15^{\circ} 41'$ .

**RUDOLPHIA**, in *Botany*, a genus established by Willdenow, in the Transactions of the Society *Nature Scrutatorum* at Berlin, v. 3. 151, is named in honour of Charles Almund Rudolph, a German physician, the author of some botanical observations. Such at least is the account of De

Theis, taken probably from the above publication, which we have not seen. The genus may also serve as a memorial of John Henry Rudolph, author of an inaugural dissertation on such plants of the *Flora Jansenfis*, as belong to the *Polyandria Monogynia* of Linnæus; see *Dryandr. Bibl. Banks.* v. 3. 161.—Willd. Sp. Pl. v. 3. 918. Poiret in Lamarck Dict. v. 6. 331.—Class and order, *Diadelphia Decandria*. Nat. Ord. *Papilionaceæ*, Linn. *Leguminosæ*, Juss.

Ess. Ch. Calyx two-lipped. Standard of the corolla very long, lanceolate. Stamens all connected. Legume flat, with many seeds.

1. *R. volubilis*. Twining Rudolphia. Willd. n. 1.—“Leaves ovate, pointed; heart-shaped at the base, and somewhat peltate.”—Native of very lofty mountains, in the West Indian island of Porto Rico. The stem is shrubby, without prickles, twining up the trunks of trees; its bark black and warty; the young branches downy. Leaves simple, alternate, stalked, rigid, entire; shining on the upper side; downy when young. Footstalks with two joints, channelled between them, on the upper side. Clusters scattered, thrice the length of the leaves. Flower-stalks three together. Flowers scarlet. Willdenow.

2. *R. peltata*. Peltate Rudolphia. Willd. n. 2. (*Erythrina planifolia*; Linn. Sp. Pl. 993. *Corallodendron folio singulari oblongo, siliquâ planâ*; Plum. Ic. 92. t. 102. f. 1.)—Leaves oblong-lanceolate, somewhat heart-shaped, peltate.—Native of Hispaniola. Willdenow asserts this to be distinct from the foregoing. The common flower-stalk, as represented by Plumier, is a foot and half long, racemose at the extremity.

M. Poiret reduces to this genus the *Butea* of Koenig, and we heartily wish we could follow him, in order to get rid of a name so absurd and reprehensible in its original application; see **PLASO** and **BUTEA**. We fear however that neither the character of the legumes, nor the habits of the plants, will support such a measure.

**RUDOLPHINE TABLES**. See **CATALOGUE of the Stars**.

**RUDOLSTADT**, or **RUDELSTADT**, in *Geography*, a town of Germany, in the county of Schwartzburg Rudolstadt, from which a branch of the house of Schwartzburg derives its title, situated on the Saal; 24 miles S.E. of Erfurt. N. lat.  $51^{\circ} 40'$ . E. long.  $11^{\circ} 19'$ .

**RUDRA**, in *Mythology, a name of the Hindoo deity Siva. In some of their theogonical books, Siva, in the form of Rudra, is made to spring from a wrinkle in the forehead of Brahma, with five heads and ten arms, as he is represented in the plates of the Hindoo Pantheon. When five-headed, he is named Pancha-muki. (See that article.) Rudra is said to have thus sprung into a new form, to enable Brahma to people the world with suitable inhabitants; his earlier efforts having been productive of a refractory race. (See **MUNI**.) The name of Rudra is generally applicable to Siva, in his character of Fate and Destiny, and of Time. Under the article **MAHAKALA** he is called Kal-Agni-Rudra, interpreted Time, Fire, Fate, and designative of his destructive energies. (See **KAL-AGNI-RUDRA**.) In the Institutes of Menu, (see **MENU**), the “eleven Rudras” are mentioned, but it has not been explained what that number especially adverts to. Rudra is understood to be the deity of pregnant women, as is his consort, known as such in her character of Rudri, or Rudrani. (See **RUDRANI**.) He is also called the god of tears and lamentation; being, as time or fate, the lord of punishment, and thereby causing these results. Sometimes he is called Maha Rudra, or the great Rudra. This occurs in an extract in the article **KAMA**.*

**RUDRANI**, or **RUDRI**, is a name and form of the goddess

goddess Parvati, considered then as the fukti or energy of her lord Siva, in his form of Rudra. (See those several articles; also RAUDRI.) In this character she is sometimes called the patroness of pregnant women. (See IDITA, ILITA, and ILITHYA.) She is invoked under the appellation of "Rudrani the beloved of Siva," in the article LAKSHMI of this work.

RUDSTAKES, in *Agriculture*, a provincial term applied to the itakes to which cattle are tied in the stall.

RUDTSDORF, in *Geography*, a town of Bohemia, in the circle of Chrudim; nine miles E. of Leutnischl.

RUE, PIERRE DE LA, in *Biography*, an ecclesiastical composer in the first stage of correct counterpoint. He was contemporary with Josquin, and one of the composers for the papal chapel during the pontificate of Sixtus IV. who reigned from 1471 to 1484. De la Rue, or as he is called by writers in Latin, Petrus Platenfis, was one of the most voluminous composers of this early period. What country gave him birth, is now difficult to ascertain; Walther calls him a Netherlander; Glareanus, a Frenchman; others suppose him to have been a Spaniard. It is, however, certain that he was in high favour with prince Albert, and princefs Isabella, of the Low Countries; that a work under his name was published at Antwerp, with this title: "El Parnasso Espanol de Madrigales y Villancicos a quatro, cinco y seis voces;" besides masses and motets to Latin words; and that he was a very learned contrapuntist.

Many of his compositions for the church are still extant in the museum collection of masses and motets, some of which were published as early as the year 1503, immediately after the invention of musical types.

RUE, CHARLES DE LA, a learned French Benedictine monk, was born at Corbie, in Picardy, in the year 1684. He took the vows at the age of 19, in the abbey of Meaux, having already given evidence that he possessed a studious disposition, by the progress which he had made in the languages, and in the belles lettres. In 1712 the learned Montfaucon admitted him into his friendship, became the guide of his studies, and freely communicated to him the stores of knowledge which he possessed. So well did the pupil avail himself of these advantages, that he soon became a very useful assistant to his master in his learned labours. In 1713, Montfaucon had published the remains of Origen's "Hexapla," and de la Rue was fixed on to give a complete edition of that learned father's works, with the exception of the Hexapla. In 1733 he published the two first volumes, with proper prolegomena, and many useful as well as very learned notes. The other volumes were published by his nephew Vincent, whom he had associated with himself in his work, after the death of Charles, which happened in 1739. The manner in which the third and fourth volumes of this great work were executed, shews that the nephew was fully adequate to the task confided to him. This edition is entitled "Origenis Opera omnia, quæ Græcè vel Latine extant, et ejus nomine circumferuntur, ex variis Editionibus et Codicibus Collecta, recensita, Latine versa at Annotationibus illustrata." Vincent de la Rue died in the year 1762. Moreri.

RUE, in *Botany*. See RUTA.

RUE, in the *Materia Medica*, the ruta graveolens, or common rue, has a strong, ungrateful odour, and a bitter, hot, penetrating taste; the leaves are so acrid as to irritate and inflame the skin, if they be much handled; and in its natural and uncultivated state, it is said to possess these qualities more powerfully. Its virtues are extracted both by water and rectified spirit, but more powerfully by the latter. On inspissating the spirituous tincture, very little of its flavour

rises with the menstruum; most of the active parts of the rue being concentrated in the extract. In distillation with water, an essential oil separates, which is of a yellowish or brownish colour, a moderately acrid taste, and penetrating smell; the decoction, inspissated, yields a moderately warm, pungent, and bitterish extract. The seeds and capsules contain more oil than the leaves. From the experiments of Beauré it appears, that the recent plant contains but a very small portion of essential oil: thus, from 21 lbs. of the leaves he scarcely obtained a drachm, while 10 lbs. of the seeds yielded two ounces.

Rue was much used by the ancients, who ascribed to it many excellent qualities. Hippocrates commends it as a resolvent and diuretic, and attributes to it the power of resisting contagion, and the action of other kinds of poisons; so that it was employed with this intention by Mithridates (see Plin. N. Hist. l. 28. c. 8.): this quality, though allowed by Boerhaave, is now generally discredited. (Cullen's Mat. Med. vol. ii. p. 365.) According to Bergius, it is "alexiteria, pellens, emmenagoga, sudorifera, rubefaciens." It is, however, acknowledged to be a powerful astringent, and, like other medicines of the fetid kind, to possess attenuating, deobstruent, and antispasmodic powers, and to be peculiarly adapted to phlegmatic habits, or weak and hysterical constitutions, suffering from retarded or obstructed secretions. A strong infusion of it, exhibited per anum, has been found of great service in relieving the convulsions of infants, arising from flatulence and other intestinal irritations. It is employed by some as a tea, and also externally in discutient and antiseptic fomentations. Among the common people, the leaves are sometimes taken with treacle, on an empty stomach, as anthelmintic. A conserve, made by beating the fresh leaves with thrice their weight of fine sugar, is the most commodious form for using the herb in substance. The dose of the powdered leaves may be from grs. xv to ℥j, given twice or thrice a day.

The officinal preparations are *oleum rutæ*, and *extractum rutæ graveolentis*. The "oleum herbæ florecentis rutæ" of the Dublin pharmacopœia, or oil of rue, is procured in the quantity of 59 grains of oil from 21 pounds of rue, which oil has the strong ungrateful odour and taste of the plant. When recently drawn the colour is yellow, but by age it deepens to a brown, and deposits a brownish resinous sediment. It congeals at 40° Fahrenheit. This oil is stimulant, and antispasmodic: it is sometimes given in hysteria, and the convulsive affections of infants attendant on dentition, and is sometimes used as a rubefacient in palsy. The dose is from ℥ij to ℥v, triturated with sugar or mucilage. The "extractum foliorum rutæ graveolentis," Edin. "extractum foliorum rutæ," Dub., or extract of rue, is prepared by the former dispensatory in the same manner as the extract, and by the latter, like other simple extracts: and by whichever process it is prepared, it is inodorous, but has a bitter acrid taste. The medicinal properties are different from those of the plant, the stimulant and narcotic powers of which depend on the volatile oil it contains, which is dissipated during the inspissation of the extract. The dose is from grs. x to ℥j, in pills. Lewis. Woodville. Thompson.

RUE, *Dog's*. See SCROPHULARIA.

RUE, *Goat's*. See GALEGA.

RUE, *Meadow*. See THALICTRUM.

The leaves of meadow-rue, mixed with other greens, are somewhat laxative, according to Dodonæus; but a decoction of the root is more so, and may be well substituted for rhubarb.

**RUE**, Wall, or *White maidenhair*, *ruta muraria*, a species of *asplenium*; which see.

This plant is found growing out of the joints of old walls in various parts of England, where it is gathered for medicinal use; but as it cannot be cultivated in gardens so as to grow to advantage, it is needless to say more of it.

This is one of the five capillary herbs mentioned in the Dispensatory, and has the same virtues with the rest of the maiden-hairs; it is sometimes used in pectoral decoctions and diuretic apozems.

**RUE**, *Wild Assyrian*. See PEGANUM.

Its virtues agree with the garden rue, but it is more acrimonious.

**RUE**, in *Geography*, a town of France, in the department of the Somme, and chief place of a canton, in the district of Abbeville; 12 miles N.W. of Abbeville. The place contains 1346, and the canton 9736 inhabitants, on a territory of 332½ kilometres, in 16 communes. The chief trade of this town is in fish, sheep, wool, horses, and cattle.

**RUE**, a river of Wales, in the county of Montgomery, which runs into the Severn, three miles S. of Welshpool.—Also, a river of France, which runs into the Dordogne, near Bort.

**RUE Ruw**, a town of Switzerland, in the canton of Friburg, capital of a bailiwick; 10 miles W. of Gruyeres.

**RUEBLAND**, a town of the duchy of Carinthia; six miles S.S.E. of Spital.

**RUECCO**, a river which rises in Carniola, and runs into the sea a little to the N.E. of Trieste, passing during its short course through immense rocks.

**RUEDA**, a town of Spain, in the province of Leon; 11 miles E.S.E. of Leon.—Also, a town of Spain, in the province of Leon; 16 miles S.W. of Valladolid.

**RUEDOCK**. See RUADOCK.

**RUELLE**, a French term, formerly introduced into our language, is a diminutive of *rue*, *street*, and signifies, literally, *little street*.

Its use, among us, was for an alcove, or other genteel apartment, where the ladies receive visits either in bed or up. The poets go reading their works from ruelle to ruelle, to bespeak the approbation and interest of the ladies. The term, however, is now disused.

**RUELLIA**, in *Botany*, a genus of Plumier's, named in honour of a French physician and botanist, Dr. John Ruelle, who published, in 1536, a treatise "De Naturâ Stirpium," chiefly a translation of Dioscorides, which is celebrated by Plumier for the excellence of its latinity. Ruelle, though physician to Francis I., quitted the profession of physic, and entered into the church. He died a canon of Paris, in 1537.—Plum. Gen. 12. t. 2. Linn. Gen. 324. Schreb. 423. Willd. Sp. Pl. v. 3. 362. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 4. 56. Pursh 420. Brown. Prodr. 477. Dill. Elth. t. 248 and 249. Juss. 103. Lamarck Dict. v. 6. 337. Illustr. t. 550. Gærtn. t. 54.—Class and order, *Didynamia Angiospermia*. Nat. Ord. *Personata*, Linn. *Acanthi*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, permanent, divided, more or less deeply, into five linear, acute, straight, equal, permanent segments. *Cor.* of one petal, somewhat irregular; the upper part of the tube dilated and inclining; limb five-cleft, spreading, obtuse; the two upper segments most reflexed. *Stam.* Filaments four, shorter than the corolla, situated in the dilated part of the tube, approaching each other, and connected, in pairs; anthers scarcely projecting beyond the tube, each with two parallel, simple cells. *Pist.* Germen superior, roundish; style thread-shaped, the length of the stamens; stigma in two acute segments, the

lowermost involute. *Peric.* Capfule nearly cylindrical, pointed at each end, almost sessile, of two cells, and two valves, separating by the elasticity of their taper base. Partition contrary to the valves, and combined with them. *Seeds* several, roundish, compressed, each subtended by an awl-shaped, ascending prop.

Eff. Ch. Calyx in five deep, equal segments. Corolla somewhat bell-shaped, slightly irregular. Stamens approximated in pairs. Anthers of two parallel cells. Capfule of two elastic valves, and two cells; partition from the centre of each valve. Seeds several, with awl-shaped props.

This genus has generally been supposed, by botanists of the Linnæan school, to differ from *Justicia*, merely in having four stamens instead of two. The elastic bivalve capfule, with props to the seeds, was considered as common to both, and very justly; though a few species have been admitted, in which these characters are altogether wanting, as *R. balsamea* and *uliginosa*.

Mr. Brown has investigated *Ruellia* with no less care than *JUSTICIA*, see that article; for indeed a student of tropical plants could not fail soon to discover, that he was able to proceed but a very little way, without understanding these genera, and the family to which they belong. The able botanist just mentioned separates from *Ruellia* all species that have only two seeds in each cell, such as *R. intrusa* of Vahl, and the Linnæan *Justicia gangetica*; and even these, he thinks, require subdivision. Others are to be removed on account of their separate partition, unconnected with the valves of the capfule, like *R. Blechnum*, &c. *R. depressa* belongs, it seems, to a different natural order.

The number of species, which in Willdenow is 46, becomes thus greatly reduced. In the new edition of Hort. Kew. eleven are, under Mr. Brown's inspection, enumerated, two of them not among Willdenow's. Four more are described in his own Prodomus, from New Holland. To all these *reptans* of Forster, and probably *secunda* of Vahl, are to be associated, nor is it supposed that several more species may not be found. We shall exhibit these acknowledged ones (only omitting *ringens*; see *HYGROPHILA*), as a specimen of the genus, several of them being much recommended by their beauty. Unfortunately they mostly require the heat of a stove, a few only will succeed with the protection of a green-house, in this country. They are generally perennial herbs; sometimes shrubby.

1. *R. ovata*. Ovate-leaved *Ruellia*. Cavan. Ic. v. 3. 28. t. 254. Willd. n. 4. Ait. n. 1.—Leaves sessile, elliptic-oblong, acute at each end, entire, villous. Flowers axillary, ternate, nearly sessile. Stem decumbent.—Native of Mexico, from whence it was transmitted to the botanic garden at Madrid. The late marchioness of Bute sent it to Kew in 1800. This is a perennial, herbaceous, stove-plant, flowering in July and August. The root is fibrous. Stems scarcely a span long, obscurely quadrangular, leafy, hairy; prostrate at the base; ascending at the extremity. Leaves opposite, near two inches long, soft, downy and fringed. Flowers about the top of the stem, large, longer than the upper leaves, deep blue with a white tube. Stigma, according to Cavanilles, spatulate, undivided.

2. *R. strepens*. Whorled *Ruellia*. Linn. Sp. Pl. 835. Mant. 422. Willd. n. 5. Ait. n. 2. Pursh n. 1. (*R. strepens*, capitulis comosis; Dill. Elth. 330. t. 249.)—Leaves stalked, ovate, acute, entire. Stalks three-flowered, very short. Stem erect.—Native of North America. On dry hills, in shady woods, from Virginia to Carolina, flowering in June and July. Pursh. Stem square, with a few short branches. Leaves two inches long, roughish with short scattered hairs. Flowers large, pale blue, making two or

## RUELLIA.

three apparent whorls, from the upper leaves. *Braçteas* lanceolate, fringed, rising above the *calyx*, whose segments are awl-shaped, very narrow, and hairy, rather longer than the ripe *capsule*.

3. *R. patula*. Spreading Ruellia. Jacq. Misc. 2. 358. t. 119. Willd. n. 6. Ait. n. 3.—Leaves stalked, ovate, entire, very obtuse, downy. Flowers ternate, nearly sessile. Stem much branched, spreading. Capsule above twice the length of the *calyx*.—Native of the East Indies; imported by sir J. Banks, in 1777. This is a shrubby species, flowering copiously in the stove, in July and August. The *leaves* are shorter and broader than in the foregoing, rounded, and somewhat heart-shaped. *Flowers* light blue. *Calyx* small. The whole plant is finely downy.

4. *R. laetea*. White Mexican Ruellia. Cavan. Ic. v. 3. 28. t. 255. Willd. n. 9. Ait. n. 4.—Leaves stalked, ovate, fringed, slightly toothed. Stalks about three-flowered, very short. Stem woolly, erect. Capsule shorter than the *calyx*.—Native of Mexico. It has been dispersed from the garden of Madrid, to different parts of Europe, and proves a tolerably hardy green-house plant, flowering in summer. The *stem* is herbaceous, erect, a foot high, square, covered with long, dense, woolly hairs. *Leaves* three or four inches long, and two broad. *Flowers* of a pale blueish-white, the central one without *braçteas*. Segments of the *calyx* hairy, very long and slender.

5. *R. clandestina*. Covert-flowering Ruellia. Linn. Sp. Pl. 885. Willd. n. 10. Ait. n. 5. (*R. capfulis teretibus*; Dill. Elth. 328. t. 248).—Leaves stalked, oblong, obtuse, somewhat toothed; tapering at the base. Stalks three-flowered, rather shorter than the leaves. Capsule nearly cylindrical, longer than the *calyx*.—Native of Barbadoes and Santa Cruz. A perennial stove plant, flowering in July and August, but seldom cultivated. The *root* consists of many long, thick, fleshy fibres. *Stem* a span high, clothed with numerous, large, undulating *leaves*. *Flowers* large, blue, on slender elongated stalks. *Calyx* linear and very narrow, scarcely above half the length of the *capsule*, which is obscurely quadrangular when ripe, containing a great number of flat, downy *seeds*, bordered with a white membrane. The *corolla* of the earliest flowers is said to be small and imperfect.

6. *R. paniculata*. Panicked Ruellia. Linn. Sp. Pl. 885. Willd. n. 18. Ait. n. 6. (*Speculum veneris majus*, *impatiens*; Sloane Jam. v. 1. 158. t. 100. f. 2.)—Leaves ovate, pointed, rough, entire. Stalks many-flowered, forked, divaricated, longer than the leaves. Upper segment of the *calyx* rather the broadest. Native of the West Indies. Sloane speaks of it as common about Kingston in Jamaica, growing among bushes. Miller and Linnæus cultivated this plant, and it may be met with sometimes in stoves, flowering in summer. The habit is somewhat shrubby, and the herbage hoary. *Leaves* copious, from two to four inches long, on stalks about half their length. *Flower-stalks* axillary, chiefly about the upper part of the stem, and extending beyond the leaves, so as to give the whole plant a panicked appearance. *Braçteas* oblong, obtuse. Each *flower* is nearly sessile, of a bright light blue, with a long slender tube. Segments of the *calyx* hispid, linear, very narrow, one of them twice as broad as the rest. Sloane says the *capsule* throws out the *seeds* with violence, when it is either touched or wetted at the end.

7. *R. tuberosa*. Tuberous-rooted Ruellia. Linn. Sp. Pl. 885. Willd. n. 19. Ait. n. 7. (*Gentianella flore cæruleo*, *integrò vasculo seminali ex humidis contactu impatiens*; Sloane Jam. v. 1. 149. t. 95. f. 1.)—Leaves ovate-wedge-shaped, crenate. *Flower-stalks* deeply-three-cleft.

*Stem* simple.—Native of Jamaica, in bushy places near Kingston, flowering after the rainy season. The perennial *root* consists of many long fleshy knobs. *Stem* erect, herbaceous, a foot high, a little hairy. *Leaves* spreading, minutely and sparingly hairy, each tapering down into a long *footstalk*. *Flower-stalks* slender, axillary, solitary, shorter than the leaves. *Calyx* very long and slender, rough with close bristles. *Corolla* large, of a fine blue. *Capsule* the length of the *calyx*; we do not perceive it to be more angular than that of *R. clandestina*, though Dillenius indicates the contrary. *Seeds* numerous.

8. *R. biflora*. Two-flowered Ruellia. Linn. Sp. Pl. 886. Willd. n. 21. Ait. n. 8. (*R. oblongifolia*; Michaux Boreali-Amer. v. 2. 23? Pursh n. 2?)—"Flowers in pairs, sessile.—Native of Carolina, from whence it was sent to Kew, in 1765, by Mr. John Cree. It is kept in the greenhouse, being an herbaceous perennial, flowering in July. We have seen no authentic specimen, nor have we any further knowledge of this species than what occurs in Linnæus. *R. oblongifolia* of Michaux, suspected by Mr. Pursh to be the same plant, is described as "ascending, all over minutely and densely downy, with erect, nearly sessile, obovate-oblong *leaves*, and mostly solitary *flowers*." Pursh adds that "the *braçteas* are the length of the *calyx*, whose thread-shaped segments are the length of the tube of the *corolla*." He adds that it grows "in sandy pine woods of Georgia, flowering in June and July," and that "the *flowers* are a yellowish-blue," a colour not very intelligible to us; but the author only saw them dried.

9. *R. oeymoides*. Brazil-leaved Ruellia. Cavan. Ic. v. 5. 9. t. 416. Ait. Hort. Kew. Epit. 373.—Stem branched, erect. *Leaves* ovate, obtuse, entire, glaucous beneath. *Flowers* axillary, ternate. *Braçteas* ovate. *Calyx* tubular at the base.—Native of Mexico; cultivated in the garden of Madrid, and introduced at Kew in 1798. It is biennial, flowering in the stove from July to September, and may perhaps be perennial in its native country. The *stem* is about six inches high, branched from the bottom, somewhat downy like the rest of the plant. *Leaves* opposite, on long stalks, concave; dark green above; glaucous beneath. *Flowers* sessile, with an ovate stalked *braçtea* at the base of each. *Calyx* with a perceptible tube, though much shorter than the last; its segments awl-shaped, rather unequal. *Corolla* pale blue, with a white tube.

10. *R. formosa*. Large Scarlet Ruellia. Ait. n. 10. Andr. Repol. t. 610. Curt. Mag. t. 1400.—Leaves stalked, ovate, entire, downy on both sides. Stalks axillary, alternate, very long, with few flowers. *Corolla* somewhat ringent. Native of Brazil. Said to have been introduced into England by sir Charles Cotton, in 1808. It proves a great ornament to our stoves, which are decorated all summer long with its very large and splendid scarlet *flowers*. The *stem* is in some degree shrubby, erect, three or four feet high, square, finely hairy, as well as the rest of the herbage, whose colour is a greyish-green. *Flower-stalks* twice or thrice as long as the leaves. Segments of the *calyx* deep and linear. Lobes of the *corolla* emarginate. *Capsule* obovate, the length of the *calyx*. *Seeds* numerous, lenticular, rough. Very different from the *macrophylla* of Vahl's Symbolæ, v. 2. 72. t. 39, which, according to Mr. Brown, is no *Ruellia*, having but two seeds in each cell, and still generically different, as he thinks from *R. intrusa*, &c. mentioned in our introductory part of this article.

11. *R. fulgida*. Lesser Scarlet Ruellia. Ait. n. 11. Andr. Repol. t. 527.—Leaves stalked, ovate, pointed, crenate, hairy. Tufts many-flowered, on long axillary stalks. *Corolla* somewhat ringent, with a nearly cylindrical tube.

tube.—Native of the West Indies. It made a part of a fine collection of stove plants, brought over by the late much-lamented earl of Seaforth, and given by his lordship to A. B. Lambert, esq. This plant first flowered in Mr. Lambert's stove, in June, 1807. Its habit is shrubby. Leaves different from the last, in being crenate and wavy. Flowers remarkably abundant, their stalks assembled in a corymbose manner. Corolla of a rich orange-scarlet, but scarcely one-third the size of the *R. formosa*. Seeds with a white border.

12. *R. secunda*. Yellow Ruellia. "Vahl. Symb. v. 3. 84." Willd. n. 36.—"Leaves ovate, somewhat heart-shaped, entire, villous. Clusters axillary, turned one way."—Native of the East Indies. Herbage downy. Leaves stalked, an inch long, obtuse; the younger ones hoary, rather pointed. Footstalks widely spreading, scarcely shorter than the leaves. Clusters almost a span long; the partial flower-stalks short and distant. Bractæas fetaceous, still shorter. Calyx hairy. Corolla smooth, yellow, an inch long. Germen villous and hoary. Vahl. Mr. Brown, not having perhaps investigated the fruit of this species, has marked its genus as doubtful.

13. *R. reptans*. Creeping Ruellia. Forst. Prodr. 44. Willd. n. 37.—"Leaves stalked, ovate, obtuse, bluntly serrated. Flower-stalks terminal, somewhat spiked."—Native of the island of Tanna. We have seen no specimen, but Mr. Brown has ascertained this to be a true *Ruellia*.

14. *R. australis*. Southern Ruellia. Cavan. Ic. v. 6. 62. t. 586. f. 1. Brown n. 1.—Flowers axillary, nearly sessile, solitary or ternate. Segments of the calyx awl-shaped, rough, separate to the base. Leaves stalked, elliptic-oblong, entire, smooth. Stem diffuse.—Native of New South Wales, from whence we received specimens from Dr. White in 1792. Mr. Brown has also observed it in the tropical part of New Holland. The stem is of humble growth, rather shrubby, more or less diffuse, branched, slender, quadrangular, smooth. Leaves most crowded towards the tops of the branches, small, hardly an inch long; paler beneath. Tube of the corolla not much longer than the calyx; its limb dilated and spreading, with rounded, entire, nearly uniform segments. We know nothing of the colour. The figure in Cavanilles is not characteristic. Its flowers are much too small in the limb. The name too is faulty.

15. *R. pumilio*. Dwarf Ruellia. Brown n. 2.—"Flowers axillary, solitary, nearly sessile. Bractæas minute. Calyx smooth, tubular at the base. Leaves narrow-oblong, obtuse. Stem diffuse."—Gathered by Mr. Brown at Port Jackson, New South Wales.

16. *R. acaulis*. Humble Ruellia. Brown n. 3.—"Stem short. Leaves oblong-wedge-shaped, obtuse. Stalks axillary, single-flowered, several times longer than the capsule. Calyx nearly smooth, without bractæas."—Gathered by Sir Joseph Banks and Dr. Solander, in the tropical region of New Holland.

17. *R. bracteata*. Bracteated Ruellia. Brown n. 4.—"Flowers axillary. Bractæas leafy, large, deciduous. Tube of the corolla elongated; its limb nearly equal. Capsule with a taper base. Leaves oblong or elliptical. Stem erect."—Gathered by Mr. Brown, in the tropical part of New Holland.

By a mistake, as we presume, *R. ringens* of Linnæus is retained as such in Hort. Kew. without any remark, and even with the erroneous synonym, which is directed to be struck out in Mr. Brown's Prodr. 479, where the plant in question makes a new genus. See HYGROPHILA.

Mr. Pursh has three North American species, besides those to which we have adverted above, called *hybrida*,

*ciliosa*, and the *humifruta* of Michaux. These we dare not admit, because it does not appear that their generic characters have been critically examined by any body; at least not with a reference to the above limitations of *Ruellia*.

RUEMANNFELDEN, in *Geography*, a town of Bavaria; 36 miles E. of Ratisbon.

RUENGAS, a country of Africa, S. of Monoemugi, about S. lat. 7°.

RUERLOO, a town of Holland, in the county of Zutphen; 4 miles W. of Borekeloe.

RUESCAR, a town of Spain, in the province of Grenada; 15 miles E. of Almeria.

RUESTA, a town of Spain, in Aragon, on the Aragon; 24 miles W. of Jaca.

RUEUTZENDORFF, a town of Austria; 4 miles E.N.E. of Entzerstorff.

RUFF, or RUFFLE, in *Military Language*, a beat on the drum. Lieutenant-generals have three ruffles, major-generals two, brigadiers and governors one, as they pass by the regiment, guard, &c. See DRUM.

RUFF-trees. See ROOF-trees.

RUFFACH, in *Geography*, a town of France, in the department of the Upper Rhine; 8 miles S. of Colmar.

RUFFE, in *Ichthyology*, the English name of the *cernua*, or small gilded perch, a fish common in our rivers, and much resembling the perch in figure, though of a more slender form.

The ruffe is called by the generality of authors *cernua fluviatilis*; and by some *chærus acerina* and *aspreto*. It is called by Johnson and Charletoæ also *serollus*. Willughby, as well as these authors, has mentioned the ferollus as another species of fish; but it is proved, by observation, that they are evidently the same species. Arledi makes this fish a perch, or *perca*; and accurately distinguishes it from the other fish of that genus by the name of the perch with only one fin on the back, and with a cavernous head. In the Linnæan system it is the *PERCA Cernua*; which see.

This fish may be preserved in glass jars with fresh water, and be made very tame. It must be fed, for it cannot subsist on the animalcula of river-water, as small daæ can.

No fish shews the circulation of the blood in a finer manner than ruffles, whose fins are exceedingly transparent. Besides, it is a creature vastly tenacious of life, and will live twenty or thirty minutes out of water, without receiving much damage. Phil. Trans. N° 478. p. 26.

RUFFE, in *Ornithology*, the name of a male species of bird, the female of which is called *reeve*, and the Latin name for which is *avis pugnax*, or the fighting bird.

This species is the *TRINGA pugnax* of Linnæus; which see.

The feathers of the male assume in several parts a variety of colours; but they are distinguished by a very remarkable circle of long feathers, surrounding their necks; whence their name: on the back of their necks they have a tuft of feathers, which spread wide on both sides; these feathers around the neck are black in some birds; and in others white, yellow, or ferruginous; and they frequently differ in colour, even in the same bird; the coverts of the wings are brown or ash-coloured; the feathers on the breast black or dusky; the four exterior feathers of the tail of a cinereous brown, and the four middle barred with black and brown; the bill is black towards the end, and red at the base; the legs are yellow. In moulting they lose the neck-feathers, nor do they recover them till after their return in the following spring, when a set of small pear-shaped yellow  
pimples

pimples break out on the face above the bill. The male birds of the first year want these marks: and the older they are, the more numerous are the pimples, and the fuller and longer the ruffs. The length of the male to the tip of the tail is one foot, the breadth two; of the reeve ten inches, the breadth nineteen: the weight of the former, when just taken, is seven ounces and a half, and of the latter only four. The reeves never change their colour, which is pale brown; the back spotted with black, slightly edged with white; the tail brown; the middle feathers spotted with black; the breast and belly white; and the legs of a pale dull yellow. They come over to us in vast numbers early in the spring, and disappear about Michaelmas, building in some parts of Lincolnshire, particularly in the fenny country about Croyland. They are found also in the isle of Ely, and in the East Riding of Yorkshire, and for about three weeks at Martin-mere, in Lancashire. The reeves lay four eggs, which are white, marked with large rusty spots, in a tuft of grass, the first week in May, and sit about a month. Soon after their arrival, the males begin to *bill*, i. e. to collect on some dry bank, near a pool of water, in expectation of the females, who resort to them. Each male keeps possession of a small piece of ground, which it runs round till the grass is worn quite away, and nothing but a naked circle left; and when a female lights, the ruffs immediately fall to fighting. When a fowler discovers one of those hills, he places his net at night, and at day-break resorts to his stand; and at the first pull takes those birds that are within reach; he then places his stales, or stuffed birds, to entice those that are traversing the fen. In this way a fowler will take forty or fifty dozen in a season. When they first come over, there are many more males than females among them; but these are so continually fighting, that their numbers soon decrease below an equality. They are fed after they are taken with bread and milk, hemp-feed, and sometimes boiled wheat; to which, if expedition is required, they add sugar, and thus they become very fat. They are killed by cutting off the head with a pair of scissars; and they discharge a great quantity of blood, considering their size. They are dressed like woodcocks, with their intestines; and when killed at the proper time, they are reckoned by the epicures very delicious. Ray and Pennant.

RUFFE is also the name of a particular species of pigeon, called by Moore the *columba cucullata rudis*.

It is in shape very like that species of pigeon called the *jacobine*, but is larger, and has a longer beak. The iris of the eye is sometimes red, sometimes pearl-coloured; the feathers of the hood and chain are much longer than the *jacobine*, though they do not come down so low to the shoulders of the wings, nor are they so compact and close, but are apt to blow about with every little blast of wind, and fall more backward off the head, and lie in a rough confused manner.

It is a common thing to match the *jacobine* pigeon with this species, with intent to improve its chain by the length of the ruffe's feathers; but the event is, that the pigeon is always worse instead of better, being longer beaked, and looser in its head and chain, without any real advantage.

RUFFEC, in *Geography*, a town of France, and principal place of a district, in the department of the Charente; 34 miles S. of Poitiers. The place contains 2110, and the canton 12,668 inhabitants, on a territory of 250 kilometres, in 20 communes. N. lat. 46° 2'. E. long. 0° 17'.

RUFFI, ANTONY DE, in *Biography*, a lawyer and historian, was born at Marzeilles in 1607, and in process of time he became a counsellor in the seneschalcy of Marzeilles, an office of considerable importance, and which he dis-

charged with diligence and great integrity. He was made counsellor of state in 1654, and died in 1689, at the age of 82. His leisure time, he had, during his long life, employed in learned enquiries, of which the fruits were, 1. An elaborate "History of Marzeilles," fol. 2. "The Life of Gaspard de Sinicane, known by the name of the Chevalier de Cotte." 3. "The History of the Counts of Provence;" and he left in MS. "A History of the Generals of the Gallies." He had a son, Louis Antony, who pursued a similar line of study, and added to his father's History of Marzeilles a second volume, in an edition published in 1696. He was author, likewise, of "Dissertations Historiques et Critiques sur l'Origine des Comtes des Provence, de Venaissin, de Forcalquier, et des Vicomtes de Marzeille;" and in 1716 he published "Une Dissertation Historique, Chronologique, et Critique sur les Evêques de Marzeille." He died in 1724, at the age of 66.

RUFFIEUX, in *Geography*, a town of France, in the department of Mont Blanc, and chief place of a canton, in the district of Chambéry. The place contains 1048, and the canton 5110 inhabitants, on a territory of 100 kilometres, in 8 communes.

RUFFINUS, in *Biography*, furnamed by some authors *Toranius*, a celebrated ecclesiastical writer and scripture commentator, who flourished in the fourth and fifth centuries, was probably a native of Aquileia, but the time of his birth is unknown. Having made choice of the ecclesiastical profession, he was baptized in the year 369, and became a presbyter of the church in that city. Here he contracted a most intimate friendship with St. Jerome, who, in his letters to his friends, extolled in the highest terms the virtues and sanctity of Ruffinus, though at a later period he proved his most bitter enemy. In or about the year 371 Ruffinus quitted Aquileia, with the determination of devoting himself to the austerities of the monastic life, under the monks in the deserts of Egypt. Coming to Rome in his way to Africa, his design recommended him to the confidence of Melania, a Roman widow of noble family and vast opulence, who resolved to accompany him to that country, and to expend her riches in the establishment of monastic and charitable institutions. In Egypt, Ruffinus spent several months in conversing with the monks, whose solitary cells were scattered throughout the deserts of Nitria, and in attending the lectures of Didymus, master of the catechetical school in Alexandria. By the Arians, who at this time were protected by the emperor Valens, Ruffinus was persecuted, thrown into prison, cruelly treated, and at length banished to a distant desert. His female friend, Melania, however, found means to purchase his redemption, and removed with him from Egypt into Palestine, where they visited the holy place, and took up their residence at Jerusalem. In this city, Ruffinus, supported by the munificence of his patroness, built a convent for upwards of fifty females, who renounced the world and devoted themselves to a religious life, over whom Melania presided. Connected with this convent were apartments for the accommodation of the pilgrims who came to visit the holy city, and who were received, and hospitably entertained, at the expence of the foundress. Here Ruffinus spent all his leisure time in study and composition. About the year 390, a violent quarrel arose between Epiphanius, and John, patriarch of Jerusalem, concerning the opinions of Origen, in which Ruffinus took such a part as to give great offence to his friend Jerome. Their friendship was now broken off, but was in a few years renewed through the mediation of Theophilus, patriarch of Alexandria. In the year 397, Ruffinus and Melania took their leave of Jerusalem, and embarked for Italy.

Italy. Having arrived at Rome, Rufinus almost immediately published a Latin version of the first book of the "Apology for Origen," which was followed by another piece, intended to prove that the works of Origen had been corrupted and interpolated, and a defence of him drawn up from his own letters. At this period our author published his translation of Origen's "Book of Principles," with a preface, in which he applauded the high opinion which, in the earlier part of his life, Jerome had entertained of that author and his writings. This conduct was warmly resented by Jerome, who published "An Apology" for himself, in which he attacked Rufinus in the most acrimonious terms, treating him as a heretic. About the year 400 he published an eloquent and indignant reply to the accusations in his "Two Books of Invectives." Rufinus, whatever might be the nature of his arguments, was in other respects the least powerful, and he thought it adviseable to retire to Aquileia. He was summoned to Rome by Anastasius, to vindicate himself against the accusations of Jerome, but he did not think it fit to obey the summons, contenting himself with sending a declaration of the conformity of his faith with that of the Catholic church, and stating that, with respect to his translation of Origen's work, he had neither approved nor disapproved, but barely refuted the sentiments of that writer. Not satisfied with this declaration, Anastasius condemned him as a heretic; but the papal anathema seems to have produced little effect on Rufinus, since it did not prevent him from continuing his controversy with Jerome, or interrupt his tranquillity or his studies. In the year 410, the ravages of the Visigoths in Italy, under Alaric, compelled him to fly from Aquileia, when he took refuge in the island of Sicily, where he appears to have died, either in the same or the succeeding year. Various characters have been given of this father. Mosheim observes, that "he would have obtained a very honourable place among the Latin writers of this century, had it not been his misfortune to have had the powerful and foul-mouthed Jerome for his adversary:" and Dupin acknowledges, "that though very ill used by St. Jerome, he was one of the ablest men in his time: perhaps he had not so much learning as that father, but his temper was better and less violent." His style is neat, and sufficiently pure in point of latinity. In his commentaries on divers parts of the scriptures, he explains the text in an elegant and natural way, chiefly adhering to the literal sense, without entangling himself in allegories. In his character of a translator from the Greek to the Latin, he takes considerable liberties, but he honestly acknowledges them. His original works, besides the pieces in controversy with Jerome, already noticed, comprize commentaries on different parts of the Old Testament; two books of Ecclesiastical History, added by him to his version of Eusebius, and continuing the history of the church to the death of the emperor Theodosius. Other works have been ascribed to him. The whole of what belongs to Rufinus, excepting his apologies for Origen and declaration to Anastasius, were published in a folio volume at Paris, in 1580. He translated the works of Josephus, the Ecclesiastical History of Eusebius, and many other works from the Greek to the Latin. Moreri. Dupin. Mosheim.

RUFINUS, minister of state to the emperors Theodosius and Arcadius, was a native of Eluzzo, now named Eaufe, a town of France, in the department of Gers, according to the modern divisions of that kingdom, which in the time of Rufinus was a celebrated city, and passing from the Romans to the Goths, was taken from them by Clovis. Rufinus was brought up to the profession of the law, and being possessed of a bold and ready elocution,

with much address, and an advantageous person, he attracted some considerable share of notice at the court of Constantinople, and about 390 was raised by Theodosius to the post of master of the offices. In 392 he was nominated to the consulship, with Arcadius for a colleague; and during the same year he was entrusted with the important post of prefect of the East. He disguised his ambition and other vices under the mask of piety, by which he secured the confidence of the emperor, and obtained the friendship of Ambrose, and other dignified ecclesiastics. Having built a sumptuous palace and church at Chalcedon, he assembled the most illustrious bishops of the East to assist at the dedication, taking occasion, at the same time, to receive the rite of baptism, which in that age was often deferred to a late period. By nature he was cruel and vindictive, and committed many atrocious acts: he stimulated his master to order the dreadful massacre of Thessalonica: he procured the disgrace and exile of the brave general Promotus, who had chastised his insolence by a blow: and he effected the ruin of the prefect Tatianus, and the execution of his son Proculus, in order to make way for his own prefecture of the East. "The punishment of the two prefects," says Gibbon, "might, perhaps, be excused by the exceptionable parts of their own conduct: the enmity of Rufinus might be palliated by the jealous and unforgivable nature of ambition. But he indulged a spirit of revenge, equally repugnant to prudence and to justice, when he degraded their native country of Lycia, from the rank of Roman provinces; stigmatized people with a mark of ignominy; and declared that the countrymen of Tatianus and Proculus should ever remain incapable of holding any employment of honour or advantage, under the imperial government."

After the death of Theodosius, in 395, Rufinus succeeded to absolute authority over the Eastern empire, in the name of Arcadius, and he made use of his power for the gratification of his passions, especially that of avarice. He exhibited a very remarkable instance of his arbitrary and violent conduct in the treatment of Lucian, who had purchased his favour, and the office of count of the East. This unfortunate person, whose administration is said to have been exemplary, affronted the emperor's uncle by the refusal of an unjust request. On the complaint of Arcadius to Rufinus, the latter, without acquainting any one with his design, set off for Antioch, and performing the journey with great celerity, entered that capital in the dead of the night, and commanded the prefect to be brought before him. Without pretending to hear any thing in proof of his innocence, he caused Lucian to be scourged to death. In the mean time his own fall was rapidly approaching. To secure his authority, and with a view of raising himself to a partnership in the empire, he had planned the marriage of his daughter to the emperor. But the chamberlain, Eutropius, contrived to place in his view Eudoxia, the beautiful daughter of Frank Bauto. He became enamoured at the sight, and Rufinus, after his return, was mortified by the emperor's marriage with his daughter's rival. This disappointment, and the fear of losing the power which he possessed, inspired him, it is said, with plotting the destruction of his sovereign, and with inviting the Huns and Goths to invade the empire, in order to create a general confusion. The famous Stilicho was at this time omnipotent in the Western empire as minister of the young Honorius, brother to Arcadius; and claiming from the appointment of Theodosius the guardianship of both his sons, he prepared to march into the East, in order to assert his authority there. At the head of the armies of both parts of the empire he had crossed the Alps, and was near Thessalonica, when Ru-

finus,

finus, dreading his approach, procured an order from Arcadius for the Eastern forces to separate from Stilicho and march to Constantinople. The general did not venture to disobey, and placed them under the command of Gainas, the Goth, with whom he had concerted his plan. The army arrived before the capital of the East, in November 395, and the emperor, with Rufinus, went out to meet it. At the distance of a mile from the capital, in the field of Mars, the troops halted. Arcadius and his minister advanced, according to an ancient custom, respectfully to salute the power that supported the throne. Rufinus expected that his partisans would take that opportunity of proclaiming him emperor, and had actually prepared the purple robe, diadem, and royal donative for the occasion. By the direction of Gainas, however, the wings wheeled round and inclosed their victim, and upon a signal given, a soldier plunged his sword into his breast. Rufinus fell, groaned, and expired at the feet of the affrighted emperor. His mangled body was abandoned to the brutal fury of the populace of both sexes, who hastened in crowds, from every quarter of the city, to trample on the remains of the haughty minister, at whose frown they had so lately trembled. His right hand was cut off and carried through the streets of Constantinople, in mockery, to extort the contributions for the avaricious tyrant, whose head was publicly exposed, borne aloft on the point of a long lance. According to the savage maxims of the Greek republics, his innocent family would have shared the punishment of his crimes; but they fortunately took refuge in a sanctuary, which protected them from the raging madness of the people, and they were permitted to spend the remainder of their lives in the exercises of Christian devotions, as they were called, in the peaceful retirement of Jerusalem.

Rufinus is said to have been well versed in elegant literature, yet a poet has been the bitterest foe to his memory. Claudian has made him the subject of two books of invectives, probably for the purpose of ingratiating himself with Stilicho, the avowed enemy of Rufinus. *Univer. Hist. Gibbon, vol. v.*

RUFISCO, in *Geography*, a town of Africa, in the kingdom of Kayor, situated on the sea-coast. Its name is a corruption of "Rio-fresco," its Portuguese appellation. It contains about 300 houses, and the inhabitants carry on a considerable trade with Europeans in slaves, skins, gum, ivory, ostrich feathers, cotton, indigo, &c.; 60 miles W.N.W. of Amboul.

RUFUS, a town of Prussian Lithuania; 20 miles N.W. of Tilsit.

RUFTER-HOOD, among *Falconers*, a plain leathern hood, large and open behind, to be worn by a hawk when she is first drawn.

RUFUMBA, in *Geography*, a town of Mombique, on the Suabo. S. lat.  $6^{\circ} 25'$ . E. long.  $35^{\circ} 30'$ .

RUFUS, the Ephesian, in *Biography*, a physician and anatomist of considerable eminence, in the reign of the emperor Trajan, was apparently entitled to the reputation which he obtained by his extensive knowledge and experience. Galen esteemed him one of the most able of the physicians who had preceded him. Rufus appears to have cultivated anatomy, by dissecting brutes, with great zeal and success. He traced the origin of the nerves in the brain, and considered some of them as contributing to motion, and others to sensation. He even observed the capsule of the crystalline lens in the eye. He considered the heart as the seat of life, and of the animal heat, and as the origin of the pulse, which he ascribed to the *spirit* of its left ventricle and of the arteries; and he remarked the

difference in the capacity and thickness of the two ventricles. He deemed the spleen to be a very useless viscus, and his successors have never discovered its use. He examined very fully the organs of generation, and the kidneys and bladder; he has left, indeed, a very respectable treatise on the diseases of the urinary organs, and the methods of cure. He also wrote a good work on purgative medicines, mentioning their different qualities, the countries from which they were obtained; and a little treatise on the names given by the Greeks to the different parts of the body. Galen affirms also that Rufus was the author of an essay on the *materia medica*, written in verse; and Suidas mentions a treatise of his on the *atra bilis*, with some other essays; but these are lost. See Sprengel, *Geschichte der Arzneikunde*, 2 theil, p. 63; and Le Clerc, *Histoire de la Médecine*, part iii. p. 104.

RUFUVEILLE, in *Geography*, a town of France, in the department of the Channel; nine miles W. of Mortain.

RUGBY, a small market-town and parish in the hundred of Knightlow, and county of Warwick, England, is situated at the distance of 19 miles E.N.E. from Warwick, 12 miles E. from Coventry, and  $84\frac{1}{2}$  miles N.W. by N. from London. This place is called Rocheberie in Domesday-book, as Dugdale conjectures, from the word Roche, signifying a rock, or quarry of stone, and Berie, a court, or habitation of note. Hence it has been supposed to have been a town of importance in early Saxon times, but the records of its remote history have entirely perished. After the Conquest it formed part of the possessions of Turchil de Warwick, from whom it was held by one Eddulfus, whose posterity continued to enjoy it till the reign of Edward I., when it was conveyed, by marriage, to the family of Goband, from whom it passed to the barons of Stafford. The situation of Rugby is lofty, and commands an extensive view over the adjacent country. The houses are disposed in the most irregular manner, and are, in general, constructed of wood. Here is a charity school, founded and endowed for the education of thirty boys, by Richard Elborow, esq.; also a grammar-school, which was founded by Laurence Sheriff, esq., in the ninth year of the reign of queen Elizabeth. The latter is a very important establishment, and is under the direction of twelve trustees, who are appointed from among the nobility and principal gentry of the county. By judicious management the property of this school, though originally trifling, has become extremely valuable, yielding a rent of 2000*l. per annum*, and when the present leases shall expire, the rent will doubtless be considerably increased. The trustees hold regular meetings for the transaction of business; and in August an annual examination of the pupils takes place before them. There are fourteen exhibitioners sent from this school to the universities, each of whom is allowed 40*l.* a-year. When vacancies occur, they are filled up at the annual examinations, which are attended by a member from both universities, appointed for the purpose by the vice-chancellor. The scholars at present amount to about 330 in number, of whom 50 are on the foundation. The old buildings of this school having been found unsuitable to its extended condition from the period of their erection, a new structure has been raised nearly on the same site, since the year 1808. This edifice is built in the style of architecture prevalent in the reign of queen Elizabeth, when the school was founded, and is admirably adapted to the purposes for which it was erected. It is composed of white brick, but the angles, cornices, and dressings to the windows and entrances, are of stone. The principal front extends 220 feet in length, and has a tower gateway in the centre, which leads into the principal court, a fine area 90 feet long, by 75 wide, with a plain cloister on three sides.

On the fourth side of the court are, the dining-hall for the boys in the head-master's house, and three schools for different classes; the west side is occupied by the great school, and that on the north by the French and writing schools. The head-master's house is placed at the eastern end of the fourth front; and between it and the schools is a range of building, divided into small apartments, appropriated to the use of the students. About sixty boys are thus accommodated; the remainder lodge with the other master, or at boarding-houses in the town. This building was designed and erected by Henry Hakewill, esq., architect.

The church of Rugby is not worthy of notice, but the church-yard is remarkable for various eccentric inscriptions. The market-day here is Saturday, weekly; and fairs are held on the 17th February, 31st March, 15th May, 7th July, 21st August, Monday before the 29th of September, 22d November, and 10th December. No manufacture of any importance is carried on in this town, but it has acquired a small trade for the supply of the adjacent country, since the formation of the Oxford canal, which passes about a mile to the northward, and forms a branch of the system of inland navigation, which connects all the principal rivers and towns in England.

Adjoining to Rugby, on its north-eastern side, is an eminence called Castle mount, from the circumstance of its having been formerly the site of a castle. Dugdale is of opinion that this fortress was one of those erected in king Stephen's time, when he was threatened with invasion by the empress Maud, whose crown he had usurped. It was most probably demolished by order of king Henry II. in the third year of his reign. The only vestiges of it now visible are parts of the moat and some embankments.

According to the parliamentary returns for 1811, Rugby parish contains 335 houses, and 1805 inhabitants, of whom nearly 1000 reside in the town. The Antiquities of Warwickshire, &c. by William Dugdale, fol. London, 1657. Beauties of England and Wales, vol. xv. 1814, by I. N. Brewer.

RUGEL, a town of Baden, near the Rhine; 10 miles N.N.W. of Friburg.

RUGEN, an island in the Baltic, separated from the coast of Pomerania, by a strait not above a mile wide; about 60 miles in circumference, without including the indentations of the coast. Its name is said to be derived from the Rugi, who first inhabited the Pomeranian coast beyond the Oder, but afterwards removed on this side of that river, taking up their chief residence in the country called after their name. On the decease of the last prince of Rugen, duke Wartislav XI., in 1478, Rugen became united with Pomerania. In 1168 it was subdued by Waldemar I., king of Denmark, its temple was demolished, the pagan worship suppressed, and Christianity established. There the divines of Rugen became vassals to the crown of Denmark. At the treaty of Westphalia, Rugen was added to Sweden, as a particular principality. At the peace of Roschild in 1658, and also at that of Copenhagen in 1660, Denmark ceded to Sweden the whole jurisdiction, civil and ecclesiastical, which it had previously exercised over certain lands in the principality of Rugen. This island is not only encompassed by the sea, but so penetrated by it, that several other islands and peninsulas are thus formed. The soil is fruitful, particularly in all kinds of grain, so that some thousands of lasts are annually shipped off for Stralsund. It breeds likewise large flocks of cattle, and yields a large quantity of fish; but Pomerania supplies it with fuel. The nobility are numerous, and invested with considerable privileges. The

president of the provincial tribunal, who must be a native, and a nobleman, is the prefect or governor, and he is assisted in the administration by a secretary and purveyor. Rugen contains 27 parishes, and 21,240 inhabitants. Its capital is Bergen. N. lat. 54° 30'. E. long. 13° 30'.

RUGENWALDE, a town of Hinder Pomerania; 20 miles N.E. of Coflin. N. lat. 54° 33'. E. long. 16° 7'.

RUGGA, a town of Africa, in Tunis, anciently called "Carago;" 40 miles S. of Cairoan.

RUGGARD, a town of Denmark, in the island of Funen; 10 miles W. of Odenfee.

RUGGED ISLE, a small island near the S. coast of Ireland, and county of Cork. N. lat. 51° 30'. W. long. 9° 2'.

RUGGED Point, a cape on the N. coast of Cumbava. S. lat. 8° 9'. E. long. 118° 58'.

RUGGIOLA, a fort of Spanish slate, serving in many places in the room of tiles and brick. It is a flaky stone of the nature of some of our grey slates, and is cut out of a mountain near Cordova; a plate of this being well heated on both sides, will retain its warmth for twenty-four hours.

The people of Cornwall and some parts of Yorkshire use a stone, which is of a talcky nature, to warm themselves when in bed, applying it at the feet of the bed. This they call the warming stone, from its use, and it will retain a sensible heat six or eight hours, after once moderately warming. Plot's Oxfordshire, p. 258.

RUGLERSREUT, in *Geography*, a town of Saxony, in the principality of Culmbach; three miles N. of Gefrees.

RUGLES, a town of France, in the department of the Eure, and chief place of a canton, in the district of Evreux; 21 miles S. of Evreux. The place contains 1564, and the canton 12,105 inhabitants, on a territory of 240 kilometres, in 26 communes.

RUGLEN. See RUTHERGLEN.

RUGMAN, JONAS JOHN, in *Biography*, a learned Iceland, was born in 1636, and received his early education at the school of Hulm. He afterwards set out for Copenhagen, in order that he might enter himself at the university, but Denmark and Sweden being, at that time, engaged in war, he was made prisoner on the way, in 1658, and carried to Gottenburg, where he was patronized by a person named Brahe, who placed him at Wissenborg school, whence he was sent to the academy of Upsal, with a pension from the king. He became acquainted with Olof Verelius, the Swedish historian and antiquary, who, immediately after the peace, sent him to Copenhagen, and thence to Iceland, for the purpose of collecting ancient manuscripts, a great number of which he brought to Sweden. He went again to Copenhagen in 1665, and brought back with him a transcript of Olof Trygvessen's History, "Ex Codice Wormiano Membranaceo." When the college of antiquities was established at Upsal in 1667, he was one of the earliest members, but died in two years afterwards, at the age of 43. He was author of many learned works, the titles of which are given in the General Biography. Among them may be mentioned "Fragmenta quædam Legum veterum collecta ex diversis Scriptoribus et Historiis, Lingua eadem;" "Versio Svecica Historiæ Veteris Islandicæ Lingua scriptæ de Regibus Norvægorum, quæ vulgo Konuriga-Sagur nuncupantur." Gen. Bio.

RUGOSUM, FOLIUM, in *Botany*. See LEAF.

RUGUPORUM, in *Geography*, a town of Hindoostan, in Golconda; 25 miles S.W. of Warangole.

RUHELAND, a town of Germany, in the principality of Blankenburg; five miles S.S.W. of Blankenburg. RUHLA,

**RUHLA**, a town of Saxony, in the principality of Eifenach, celebrated for its manufacture of knives; four miles S. of Eifenach.

**RUHLAND**, or **RULAND**, a town of Upper Lufatia, on the river Elfter; 27 miles N. of Dresden. N. lat. 51° 27'. E. long. 13° 50'.

**RUHNKEN**, **DAVID**, in *Biography*, an eminent critic, was born in 1723, at Salop, in Pomerania, of parents in a reputable situation of life. He received the early part of his education at his native place, after which he went to the Frederician college at Konigsberg, from whence, at 18, he proceeded to the university of Witterberg, where he paid particular attention to the lectures of Ritter on jurisprudence and history, and those of Berger on Roman eloquence and antiquities; he did not, however, neglect other important branches of study, *viz.* the mathematics and philosophy. He was intended, by his parents, for the church, and they were desirous that he should conclude his studies with a course of theology; but the ardour which he had imbibed for philological enquiries induced him to repair to Leyden, where the learned Hemsterhuys was then in the height of his reputation. To this professor he particularly attached himself, who, in return, recommended him several private pupils. Ruhnken resolved to settle in that country, as well on account of the select society, as of the philosophical liberty for which Holland was, at that period, peculiarly distinguished. In the year 1749, being the sixth year of his residence at Leyden, he first made himself known as a critic by a Latin epistle to the celebrated Valekenær on Homer's hymns, and Hesiod, which was followed, in 1751, by another to Ernelti, on Callimachus and Apollonius Rhodius. Both of these displayed consummate skill in the Greek language, with great compass of erudition and elegance of taste. At this time, by the advice of Hemsterhuys, he renewed his study of jurisprudence, in order to qualify himself for a professorship, those of polite literature being pre-occupied; and in 1752 he edited some Greek commentaries upon a part of the Code and Digest with a Latin version and learned notes. He next edited "Timæi Lexicon Vocabularum Platoniarum," a piece which gave full scope to that grammatical criticism in which he particularly excelled. "This," according to the learned Brunk, "in the whole circle of Greek literature, is both the shortest and most learned work." In the year 1755, Ruhnken visited Paris, where he remained a year most assiduously occupied in copying and collating MSS. in the public libraries. After his return, in 1757, he was appointed reader of the Greek in the university, and upon this occasion he pronounced an oration "De Græcis Artium et Doctrinarum Inventrice." In four years after this, he succeeded to the chair of history and eloquence, delivering for his inaugural speech an oration "De Doctore Umbratico." By this appellation, says his biographer, he meant to characterize the man of letters who confines himself to the *stade* of his own school, surrounded by admiring scholars, and shunning the commerce of the world at large; and the picture which he drew was so well delineated, that it gave offence to certain persons who supposed it to be designed as a portraiture of themselves. About this period he refused a professorship at Gottingen, recommending Heyne to fill the office. In his forty-first year he married a beautiful young woman of eighteen, by whom he had two daughters, but the comfort of this alliance was, in a few years, destroyed by an apoplectic attack, which deprived his wife of sight and speech. He seems hitherto to have lived in a social unshackled manner, enjoying the company of his friends, and participating in all

common amusements. He was remarkably fond of hunting, or rather coursing, a sport of which he was a great master, few surpassing him in the breed of his greyhounds, or in agility in leaping over the water-ditches, so frequent about Leyden. This pastime, apparently so very uncongenial to a literary mind, he continued almost to the last year of his life, and he thought it enabled him to resume his studies with peculiar spirit and effect. In the year 1767 he was Rector Academiæ, and on quitting his office he pronounced a very elegant eulogy on Hemsterhuys, who had died in the preceding year. In 1774 he was made librarian to the university, in which station he took great pains in making additions to the stock of valuable books. He preserved his health to an advanced age, till at length he became subject to catarrhal and dropsical complaints, under which he sunk in May 1798, in the 76th year of his age. He was the editor of many learned works, among which are the following: "Rutilius Lupus," with "Aquila Romanus," and "Julius Rufianus;" "De Figuris sententiarum;" "De Vita et Scriptis Longini;" "Velleius Paterculus;" "Homer's Hymns;" a very much enlarged edition of "Timæi Lexicon;" an edition of the "Works of Muretus;" the two last were published in the year 1789. He afterwards employed himself in an edition of the Scholiasta of Plato; and an improved edition of Scheller's Latin dictionary. This learned man placed all his glory in philological acquirements, which he seemed to regard as the highest species of knowledge. He not only made very light of theological studies himself, but discouraged them in all young men who possessed strong natural talents and promising abilities. A very tenacious memory had stored his mind with a vast mass of critical matter, especially of every thing that related to grammar, which he applied with much clearness and sagacity. He was one of the most correct Grecians of his age, and was surpassed by none in the purity and elegance of his latinity, both in speaking and writing. He left very little property behind him, excepting a library, rich in valuable printed books and manuscripts, which were purchased by the states of Holland for the university of Leyden, upon the condition of annuities for life to his widow and daughters.

**RUHR**, in *Geography*. See **ROER**.

**RUHRORT**. See **ROERORT**.

**RUHTE**, a town of Westphalia, in the bishopric of Hildesheim, at the conflux of the rivers Innersee and Leine; seven miles N.W. of Peine.

**RUJAMPET**, a town of Hindooistan, in Tellingana; 22 miles S. of Ramgur.

**RUIB**, a small island in the Pacific ocean, near the coast of Waygoo. N. lat. 0° 4'. E. long. 130° 20'.

**RUIJUEAH**, a town of Hindooistan, in Lahore; 36 miles W. of Lahore.

**RUINART**, **THIERRY**, in *Biography*, a learned French writer, who flourished at the close of the 17th and at the beginning of the 18th centuries, was born at Rheims among the Benedictine monks of the congregation of St. Maur, and, after going through the usual course of philosophy and divinity in the abbey of St. Peter at Meaux, devoted his chief attention to the study of the sacred scriptures, the fathers, and the ancient ecclesiastical writers. These branches of learning he cultivated with so much ardour and success, that he was soon selected by father Mabillon to be his assistant in his learned labours. In 1689 he shewed his talents as an author, by publishing at Paris "Acta primorum Martyrum sincera et selecta, collecta et edita cum notis," with a learned preface, in which

which he undertakes to refute the hypothesis of Dodwell, "De paucitate Martyrum." This work was several times reprinted with considerable additions. The next publication was an improved edition, in 1694, of "Victoris Vitenfis Historia Persecutionis Vandalicæ." In 1699 he published a new and greatly esteemed edition of "S. Gregorii Turgonensis Episcopi, Opera Omnia, necnon Fredegarii Scholastici Epitome et Chronicon cum suis continuatoribus et aliis antiquis Monumentis;" he was the author and editor of many other works, and in 1709 he published a sketch of the "Life of Father Mabillon," and he died in the same year at the age of 52. His works afford abundant evidence that he was a man of deep research and profound learning: they recommend themselves by their accuracy, perspicuity, and neatness of style. The author, however, was not more respected for his learning, than he was esteemed for his humility, modesty, and piety.

RUINES, in *Geography*, a town of France, in the department of the Cantal, and chief place of a canton, in the district of St. Flour; six miles E.S.E. of St. Flour. The town contains 649, and the canton 7994 inhabitants, on a territory of 275 kilometres, in 15 communes.

RUININE OIL, a name given by some authors to the oil of the palma Christi, which is very common in the West Indies, and is used by the common people in lamps. It is a delicate, sweet, and transparent oil, and has no peculiar operation in physic. They often give it in glysters from one spoonful to three at a time, and it has only the effect of common oil; but the leaves of the plant are one of the grand medicines of the Negroes; bruised and applied to the head, they are thought to be an almost infallible remedy for the head-ache, of whatever kind, or from whatever cause. See *CASTOR-Oil*.

RUINS, a term particularly used for magnificent buildings fallen to decay by length of time, and of which there only remains a confused heap of materials.

Such are the ruins of the tower of Babel, of the tower of Belus, two days journey from Bagdat, in Syria, on the banks of the Euphrates; which are now no more than a heap of bricks, cemented by bitumen; and of which we only perceive the plan to have been square.

Such also are the ruins of a famous temple, or palace, near Schiras, in Persia, which the antiquaries will have to have been built by Ahafuerus; and which the Persians now call Tchelminar, or Chelminar; *q. d.* the forty columns; because there are so many columns remaining pretty entire, with the traces of others; a great quantity of basso relievos, and unknown characters, sufficient to shew the magnificence of the antique architecture. The ruins of Palmyra may also be reckoned in the class of famous ruins.

RUISCH, RACHEL, in *Biography*, was born at Amsterdam in 1664, the daughter of Frederick Ruifch, or Ruysch, the celebrated professor of anatomy. The very early disposition she exhibited for drawing flowers, and the extreme accuracy and minuteness with which she had copied prints without assistance, induced her father to place her under the tuition of William Van Aelt, an eminent flower-painter.

In a few years she became the rival of her master, and at length surpassed him; and indeed, as far as a neat and correct imitation of a single flower, a leaf, or an insect goes, she has been equalled by few. The great defect in her productions is a want of combination, the parts being separated, and the masses weak; which is the more to be lamented, as her choice of objects was remarkably elegant, and her manner of treating them perfection itself, even to illusion.

Her extraordinary talents recommended her to the peculiar patronage of the elector palatine, who in 1708 ap-

pointed her his paintress; and he was so great an admirer of her works, that he possessed a considerable portion of them, and rewarded their author munificently. She continued to exercise her talents, with almost unimpaired success, to a very advanced period of her existence, and died at Amsterdam in 1750, at the age of 86.

RUISSEAU, GRAND, in *Geography*, a settlement in the Indiana territory, on the left bank of the Mississippi.

RUISSKAR, a small island on the east side of the gulf of Bothnia. N. lat. 61° 24'. E. long. 21° 8'.

RUIVAINS, a town of Portugal, in the province of Tras os Montes; nine miles S. of Montalegre.

RUIZIA, in *Botany*, named by Cavanilles in honour of Don Hippolito Ruiz, a Spanish botanist, who studied under the celebrated Mutis in South America, and who in conjunction with Pavon, another pupil of Mutis, published the splendid *Flora Peruviana*.—Cavan. Diff. 3. 117. Schreb. 466. Willd. Sp. Pl. v. 3. 798. Ait. Hort. Kew. v. 4. 221. Juss. 275.—Class and order, *Monadelphia Polyandria*. Nat. Ord. *Columnifera*, Linn. *Malvaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, double; outer of three, ovate, concave, acute, deciduous leaves; inner of one leaf, permanent, cloven into five, lanceolate segments. *Cor.* Petals five, obliquely sickle-shaped, rounded at the tip, undivided, flat, spreading, fastened to the bundle of stamens. *Stam.* Filaments numerous, generally from thirty to forty, shorter than the corolla, united at their base into the form of a pitcher, inclosing the germen; anthers oblong, incumbent. *Pist.* Germen superior, globose, ten-furrowed; styles ten, short; stigmas simple. *Peric.* Capsules ten, compressed, membranaceous, woody on the back, boat-shaped, of one cell, united into a globular, umbilical whorl. *Seeds* two, roundish, or slightly triangular, pointed.

Obf. This genus is nearly akin to *ASSONIA*; see that article.

Ess. Ch. Calyx double; outer of three leaves. Styles ten. Capsules ten, of one cell, with two seeds, and disposed in a circle.

1. *R. cordata*. Heart-leaved Ruizia. Willd. n. 1. Cavan. Diff. t. 36. f. 2.—Leaves heart-shaped, lanceolate, wavy.—Native of the Isle of Bourbon, where it flowers in March and April. *Stem* shrubby, branched. *Leaves* alternate, stalked, numerous, ovate, pointed, notched. *Stipulas* awl-shaped, whitish, powdery, deciduous. *Flowers* in umbel-like terminal corymbs, sulphur-coloured, each on a short stalk.

2. *R. lobata*. Lobed Ruizia. Willd. n. 2. Cavan. Diff. t. 36. f. 1.—Leaves heart-shaped, five-lobed, notched.—Found also in the Isle of Bourbon, flowering in February and March. A handsome shrub, five or six feet high, much branched, with a greyish-white bark. *Leaves* crowded together at the extremities of the branches, alternate, stalked, smooth above, white and dusty beneath, the older divided into five, rarely into seven, lobes. *Stipulas* awl-shaped, erect, downy or powdery, deciduous. *Flowers* like those of the above species in form and colour.

3. *R. variabilis*. Various-leaved Ruizia. Willd. n. 3. Jacq. Hort. Schoenbr. v. 3. 24. t. 295. (*R. palmata* and *R. laciniata*; Cavan. Dill. t. 37. f. 1, and 2.)—Leaves of the flowering branches palmate; those of the barren ones digitate.—Native of the Isle of Bourbon, and introduced at Kew, in 1792, where it flowers in May. A very handsome shrub of rather humble, but diffuse, growth. *Stems* wavy, furrowed, brown. *Leaves* alternate, stalked, dark green above, whitish underneath, extremely curious for the

variety of their shape, expressed in the specific character, and which is admirably shewn in Jacquin's figure. *Flowers* in umbel-like corymbs, of a pale red or crimson colour, with deep red claws. The name of this is by mistake engraved *R. diversifolia*, instead of *variabilis* in Jacquin's plate.

In Commerfon's MSS. this genus was called *Kanigia*.

RUKHADORFF, in *Geography*, a town of Austria; four miles N.N.E. of Sonneberg.

RUKI, a town of Mingrelia, in which the palace of the prince is surrounded with a thick wall, seated on a river which runs into the Black sea; 200 miles W. of Teflis.

RUKKIA, in *Zoology*, a name given by some to a peculiar kind of squirrel, found in the island of Ceylon.

RUKMENI, in *Hindoo Mythology*, is the name of one of the wives of Krishna, who being an incarnation of Vishnu, his heavenly consort Lakshmi, is represented to have also descended in this form of Rukmeni to accompany him. In many authorities she appears to be the same person as Radha, Krishna's favourite wife: but others make a difference, stating that Rukmeni was his legal worldly wife, and that Radha is a personification of religion. Others again say, that Rukmeni was the spiritual spouse. If, however, it be admitted, that such a person as Krishna ever existed, we may farther admit, that he had a plurality of wives, and that the two women in question were among them. A list of his wives, eight in number, will be found under KRISHNA. Rukmeni is usually the first on the list. She is said to have been the daughter of a Raja Bhishmaka; and another of her names is Kantamati. On the death of Krishna, Rukmeni, with several others of his wives, burnt themselves, in view to an immediate reunion with their lord in Vaikontha, the paradise of Vishnu. This self-immolation is called *Sati*; and under that article some account is given of it. Rukmeni is related to have borne a son to Krishna, of whom very frequent mention is made in Hindoo writings, being no other indeed than Kama, the god of love, incarnated in the person of their son Pradyamna. As the mother of the Hindoo Cupid, we here find Lakshmi (recollecting that Rukmeni is that goddess in another form) corresponding, as in many other instances, with the Venus of Western mythologists. See KAMA, LAKSHMI, PRADYAMNA, and RETI, for farther notice of these fables. Under KRISHNA, RADHA, and VAIKONTHA, will also be found some particulars connected with the subjects of this article. It may be farther noticed, that in temples dedicated to the worship of Krishna, statues of Rukmeni are commonly seen. Cats, said to be of her, are also common. In other *avatars*, or *descents* of Vishnu, his consort is said to have accompanied him under the name of Rukmeni. See hereon under WITTOBA.

RULE, or RULER, *Regula*, a very simple instrument, ordinarily of hard wood, thin, narrow, and straight, serving to direct the drawing of right lines.

The rule is of principal use in all the mechanical arts.

To prove whether or no it be just, draw a line by it on paper; then turn the rule about, the right end to the left, and apply the same edge this way to the line; if the edge now agree exactly with the line, the ruler is true.

Desmarts has a fine poem on the amours of the rule and compass. The stone-cutters' rule is usually four feet long, and divided into feet and inches.

The masons' rule is twelve or fifteen feet long, and is applied under the level to regulate the courses, to make the piedroits equal, &c.

RULE, *Parallel*, or *Ruler*. See PARALLEL.

RULE is also applied to certain instruments which have other considerable uses besides that of drawing lines. Such are the carpenters' joint-rule, Everard's and Coggeshall's sliding-rules, &c.

RULE, *Carpenters' joint*, is an instrument usually of box, 24 inches long, and  $1\frac{1}{2}$  broad, each inch being subdivided into eight parts. On the false side with these divisions is usually added Gunter's line of numbers.

On the other side are the lines of timber and board-measure, the first beginning at  $8\frac{1}{2}$ , and continued to 36, near the other end; the latter is numbered from 7 to 36, 4 inches from the other end. (*Plate VI. Surveying, fig. 14.*) The division of the timber-line is formed from a consideration, that 1728 inches make a solid foot, in the following manner: thus, 9 is so placed against one of the divisions of inches, or parts on the other side of the rule, beginning from the right hand, that its square, which is 81 inches, multiplied by that number of inches and parts, must make 1728 inches; which, dividing 1728 by 81, must be placed against  $21\frac{1}{3}$  from the right hand; and 10 must be placed against  $17\frac{1}{3}$  inches; because 1728 divided by the square of 10 or 100, gives  $17\frac{1}{3}$ , &c. But because a square whose side is 1, 2, &c. to 8 inches, requires more than 24 inches in length, as a multiplier, in order to produce 1728 inches; and since the length of the rule is only 24 inches, there is a table upon the left end of it, which supplies its defect of length. In this table the upper row of figures, *viz.* 1, 2, 3, 4, 5, 6, 7, 8, denotes inches, or the lengths of the sides of squares; and the second and third rows are the correspondent feet and inches to make up a solid foot. It is made by dividing 144 inches by the squares of 1, 2, 3, 4, 5, 6, 7, 8.

The line of board-measure is thus divided: suppose the division 7 to be marked; divide 144, the number of inches in a square foot, by 7, and the quotient will be  $20\frac{4}{7}$  inches; whence the division 7 must be against  $20\frac{4}{7}$  inches on the other side of the rule. To mark the division 8, divide 144 by 8, and the quotient, which is 18 inches, must be placed on the line of board-measure against 18 inches on the other side, &c. But because the side of a long square, that is, 1, 2, 3, 4, 5 inches, requires the other side to be more than 24 inches, the whole length of the rule; there is a table annexed, formed by dividing 144 inches by each of the numbers in the upper row, and then each of the quotients by 12, to reduce them into feet.

RULE, *use of the carpenters' joint*. The application of the inches in measuring lengths, breadths, &c. is obvious. That of the Gunter's line, see under GUNTER'S LINE. The use of the other side is all we need here illustrate.

1. *The breadth of any surface, as board, glass, &c. being given, to find how much in length makes a square foot.*—Find the number of inches the surface is broad, in the line of board-measure, and right against it, on the inches side, is the number of inches required. Thus, if the surface were 8 inches broad, 18 inches will be found to make a superficial foot.

Or, more readily, thus. Apply the rule to the breadth of the board or glass, that end marked 36 being even with the edge; the other edge of the surface will show the inches and quarters of inches which go to a square foot.

To find the content of a given surface. Find the breadth, and how much makes one foot; then turn that over as many times as you can upon the length of the surface, and so many feet does the surface contain.

2. *Use of the table at the end of the board-measure.* If a surface be one inch broad, how many inches long will make a superficial foot? Look in the upper row of figures for

7 inch, and under it, in the second row, is 12 inches, the answer to the question.

3. *Use of the line of timber-measure.* This resembles the former; for, having learnt how much the piece is square, look for that number on the line of timber-measure; the space thence to the end of the rule is the length, which, at that breadth, makes a foot of timber. Thus, if the piece be 9 inches square, the length necessary to make a solid foot of timber is  $21\frac{1}{2}$  inches. If the timber be small, and under 9 inches square, seek the square in the upper rank of the table, and immediately under it are the feet and inches that make a solid foot. Thus, if it be 7 inches square, 2 feet 11 inches will be found to make a solid foot.

If the piece be not exactly square, but broader at one end than another, the method is, to add the two together, and take half the sum for the side of the square. For round timber, the method is, to girt it round with a string, and to allow the fourth part for the side of the square. But this method is erroneous; for hereby you lose above  $\frac{1}{4}$ th of the true solidity. See *SLIDING Rule* and *TIMBER*.

*RULE, Caliber.* See *CALIBER*.

*RULE, Everard's sliding.*

*RULE, Coggeshall's sliding.* } See *SLIDING Rule*.

*RULE, Regula,* also denotes a certain maxim, canon, or precept to be observed in any art or science. Thus we say, the rules of grammar, of logic, of philosophizing, &c.

School philosophers distinguish two kinds of rules; *viz.* *theoretical*, or *rules of knowing*, which relate to the understanding, being of use in the discovery of truth; and *practical*, or *rules of acting*, which relate to the will, and serve to direct it to what is good and right.

For the management and application of these two sorts of rules, there are two distinct arts; *viz.* *logic* and *ethics*: see each respectively.

*RULES of knowing, regula sciendi,* are such as direct and assist the mind, in perceiving, judging, and reasoning.

*RULES of acting, regula agendi,* are those by which the mind is guided in her desires, pursuits, &c.

Authors are extremely divided about the regard to be had to the rules of poetry fixed by the ancients, Aristotle, Horace, Longinus, &c. and admitted by the modern critics, as Bossu, &c. some contending, that they must be inviolably observed; others pleading for liberty to set them aside on occasion. Rules, it is complained, are fetters; rank enemies to genius; and never religiously observed by any, but those who have nothing in themselves to depend on. Voiture frequently neglected all the rules of poetry, as a master who scorned to be confined by them.

The theatre has its particular rules, as the rule of twenty-four hours, the unities of action, time, and place, &c. If it be true, says Moliere, that plays conducted according to the rules do not please, but those which are not, do, the rules must be naught. For myself, when a thing hits and diverts me, I do not enquire whether I have done amiss, nor whether Aristotle's rules forbid me to laugh.

*RULES of philosophizing.* See *PHILOSOPHIZING*.

*RULE,* in *Arithmetic*, denotes a certain method of performing particular arithmetical operations, as the rules of addition, subtraction, multiplication, and division; which four are called the fundamental rules of arithmetic, all other operations being dependant on one or more of these. See *ADDITION*, *SUBTRACTION*, &c.

From the combination of these rules various others are derived, and, we must add, many more than ought to be distinctly characterized. Thus, our writers on arithmetic give us the rules of barter, simple interest, brokerage, factorage, rebate and discount, exchange, tare and tret, and a vast variety of others, which are, in fact, only so many examples

in the rule of proportion (or, as it is commonly called, the rule of three), and ought, therefore, to be included under that general term.

At a time when arithmetic and geometry formed almost the only subjects of a mathematical education, long spun-out treatises of arithmetic, and extensive elementary works on geometry, were at least excusable; but since the improvements that have been made in analysis, the two former subjects form but a very small part of what is necessary to be known, for a person to have any pretensions to the character of a mathematician; and it is, therefore, astonishing that writers on those subjects, particularly those on arithmetic, have not thought of contracting their works, by condensing under one head a number of different rules, now given under distinct titles, and transforming others, such as position, alligation, &c. to introductory treatises on algebra, to which branch they more properly belong. By a judicious arrangement of this kind, the two subjects of arithmetic and elementary algebra might be very well condensed into the usual size of an arithmetic, and a boy be made to acquire a competent knowledge of both subjects, in less time than is usually employed in taking him through arithmetic only.

*RULE of Three, or Rule of Proportion,* by some former writers called also the *Golden Rule*, is one of the most extensive and useful rules in arithmetic, teaching how to find a fourth proportional to three given numbers.

The rule of three has commonly been divided into two cases, *direct* and *inverse*, a distinction, however, which is totally useless, and which has been avoided by some of our best modern writers; it may not, however, be amiss to explain, in this place, the difference that was formerly understood between the direct and the inverse rule of three.

The *rule of three direct*, is when more requires more, or less requires less, as in this example. If 3 men will perform a piece of work, as, for instance, dig a trench 48 yards long in a certain time, how many yards will 12 men dig in the same time? Here it is obvious, that the *more* men there are employed, the *more* work will they perform; and therefore, in this instance, more requires more. Again; if 6 men dig 48 yards in a given time, how much will 3 men dig in the same time? Here less requires less; for the *less* men there are employed, the *less* will be the work done in the same time. And all questions falling under either of these cases are said to be in the rule of three direct.

The *rule of three inverse*, is when more requires less, or less requires more, as in this example. If 6 men dig a certain quantity of trench in 14 hours, how many hours will it require for 12 men to dig the same quantity? Or thus: If 6 men perform a piece of work in 7 days, how long will 3 men be in performing the same work? These examples are both in the inverse rule; for in the first, more requires less, that is, 12 men being *more* than 6, they will require *less* time to perform the same work; and in the latter, the number of men being *less*, they will require a *longer* time. All questions of this class are said to be in the rule of three inverse. These two cases, however, as we before observed, may be included under one general rule, as follows.

*Rule.*—Of the three given terms, set down that which is of the same kind with the answer towards the right hand; and then consider, from the nature of the question, whether the answer will be more, or less, than this term. If the answer is to be greater, place the less of the other two terms on the left, and the remaining term in the middle; but if it is to be less, place the greater of the two given quantities on the left, and the less in the middle; and in either case, multiply the second and third terms together, and divide by the first term for the answer, which will always be of the same denomination as the third term.

# R U L

*Note 1.*—If the first and second terms contain different denominations, they must both be reduced to the same denominations; and if the third term be a compound number, it is generally most convenient to reduce it to the lowest denomination contained in it.

*Note 2.*—The same rule is applicable, whether the given quantities be integral, fractional, or decimal.

### Examples.

If an acre of land be worth 73*l.* 1*s.*, how much land may be bought for 250*l.* 10*s.*?

#### Integral.

	364				
	12				

In many cases of commerce and accounts, we have more compendious ways of working questions that come under the rule of three than by the rule itself; which, by reason of their expediting practice, are called *practice*, and constitute a particular rule of themselves.

According to the above rule, it will be observed, that the third term is of the same kind or name as the fourth term or answer, and the second of the same name with the first; so that the analogy in both pair of terms is between quantities of the same kind; which is, in fact, necessary to constitute a proportion, according to Euclid's definition: whereas, by some strange oversight, it will be found that most of our writers on arithmetic, by making the middle term like the answer, have necessarily to consider the ratio of incongruous quantities, or at least the ratio between the abstract numbers by which they are expressed.

*Rule of Compound Proportion, or Double Rule of Three,* or, as it is otherwise called, the *Rule of Five*, is the method of solving, at one operation, such questions as would require two or more statings by the common or simple rule of three.

*Rule.*—1. Set down the terms expressing the condition of the question, in one line. 2. Under each conditional term set its corresponding one in another line. 3. Multiply the producing terms of one line, and the produced term of the other line continually, and take the result for a dividend. 4. Multiply the remaining terms continually, and let the product of them be a divisor. 5. The quotient of this division will be the term required.

By producing terms here, are meant whatever necessarily and jointly produce any effect; as the cause and the time; length, breadth, and depth; buyer and his money; seller and his goods; all necessarily inseparable in producing their several effects.

In a question where a term is understood, and not expressed, that term may be expressed by unity.

*Example.*—If 250*l.* serve six persons for nine months; how long will 1000*l.* serve four persons at the same rate?

Here the terms which express the condition are,

£ Per. Mon.

250 : 6 : 9

corresponding terms 1000 : 4 : Q

where Q is put to represent the term required.

Among the conditional terms, six persons and nine months are producing, and 250*l.* is produced: among their corresponding terms, four persons and Q are producing, and 1000*l.* is produced.

But it being impossible to multiply the producing terms in the second line, and the produced in the first, because Q is unknown; therefore, multiply the producing terms of the first line by the produced in the second, and divide by the product of the rest.

$$\text{Then will } Q = \frac{6 \times 9 \times 1000}{4 \times 250} = 6 \times 9 = 54. \text{ See}$$

Mr. Dodson's Anti-Logarithmic Canon, p. 38, et seq.

But if the notion of producing and produced terms should seem obscure, those who have a knowledge of the doctrine of compound ratios will easily perceive that, in the foregoing question, Q is to 9 months in the compound ratio of four persons to six persons inversely, and of 1000*l.*

to 250*l.* directly, that is,  $\frac{Q}{9} = \frac{6}{4} \times \frac{1000}{250}$ , therefore  $Q = \frac{6 \times 9 \times 1000}{4 \times 250} = 54$ , as before. And in like manner

may other questions, relating to the compound rule of proportion, be stated and solved, however complex.

The above rule may be expressed somewhat simpler, as follow:

*Rule 2.*—Set that term, which is of the same kind with the answer, on the right, and take any two of the other given terms which are of the same name, and consider, from the nature of the question, whether, if these three were the only given terms, the answer ought to be more or less than the above-mentioned right-hand term, and arrange these two terms accordingly, as in the rule of three.

Considering still the same right-hand term as common to every stating, take two other terms which are of the same kind, and arrange them as above, according as, in this case, the answer ought to be more or less than the right-hand term; and proceed in the same manner with every pair of terms that are of the same name. Then multiply all the first terms together for a divisor, and all the other terms together for a dividend, and the quotient thence arising will be the answer sought.

*Example.*—If 248 men, in 5 days of 11 hours each, can dig a trench 230 yards long, 3 wide, and 2 deep; in how many days, of 9 hours each, will 24 men dig a trench 420 yards long, 5 wide, and 3 deep?

Men	24	:	248	} :: 5 days, common term.
Hours	9	:	11	
Length	230	:	420	
Width	3	:	5	
Depth	2	:	3	

Then  $\frac{248 \times 11 \times 420 \times 5 \times 3}{24 \times 9 \times 230 \times 3 \times 2} = 288\frac{5}{8}$  days, the term required.

*RULE, Central.* See CENTRAL.

*RULE*, in a monastic sense, is a system of laws, or constitutions, by which religious houses are established and regulated; and which the religious make a vow to observe at their entrance.

The monastic rules are all to be approved of by the pope,

in order to make them valid. The rule of St. Benedict is, by some authors, called the *holy* rule.

Those of St. Bruno and St. Francis are, of all others, the most austere. See CARTHUSIANS.

When a religious cannot support the austerities of his rule, he sues for a dispensation.

*RULE*, in the *Canon Law*. The rule *de verisimili notitia, of probable notice*, in the Romish church renders all provisions to a benefice, vacant by death, null, if it appear, that, from the day of the decease to the day of the date of the provisions, or to the day when the courier arrives from Rome, there has not been time sufficient for regular notice of the person's decease to be conveyed to the pope.

Provisions are even null, if it be proved the courier set out before the person was deceased. This rule was, according to the old constitution, strictly observed in France; in other countries the pope finds frequent occasions to dispense with it. See PROVISIONS.

*RULE of twenty Days, Regula viginti Dierum.* By this rule, if an ecclesiastic resign his benefice, to make the resignation valid, the resigner must survive its admission in the court of Rome twenty days. If he die before the expiration of the twenty days, the resignation is void, and the benefice becomes vacant by death.

This rule does not hold of the provisions of ordinary collators; nor of simple and pure resignations into the hands of the ordinary; but only in case of provisions of the pope, dispatched on resignations *in favorem*.

This rule anciently extended to such as resigned in time of health, as well as of sickness. Pope Boniface restrained it to the latter; whence it is commonly called *regula de infirmis resignantibus*.

*RULE de Publicandis.* By this rule, the resignee of a benefice, if he have a provision from the court of Rome, is obliged to publish the resignation, and take possession within six months; or, if he have it from the ordinary collator, within one month. Otherwise, if the resigner die, the resignation becomes null.

*RULES of Court, in Law*, are certain orders made, from time to time, in the courts of law, which attorneys are bound to observe, in order to avoid confusion; and both the plaintiff and defendant are at their peril also bound to pay obedience to rules made in court relating to the cause depending between them. It is to be observed, that no court will make a rule for any thing that may be done in the ordinary course; and that if a rule be made, grounded upon an affidavit, the other side may move the court against it, in order to vacate the same, and thereupon shall bring into court a copy of the affidavit and rule. On the breach and contempt of a rule of court an attachment lies; but it is not granted for disobedience to a rule, when the party has not been personally served; nor for disobeying a rule made by a judge in his chamber, which is not of force to ground a motion upon, unless the same be entered. A rule of court is granted every day, whilst the courts of Westminster sit, to prisoners of the king's bench, or Fleet prison, to go at large about their private affairs.

*RULES, Clerk of the.* See CLERK.

*RULE Water*, in *Geography*, a river of Scotland, which runs into the Teviot, 4 miles S.W. of Jedburgh.

*RULER, PARALLEL.* See PARALLEL Ruler.

*RULLE*, in *Geography*, a town of Westphalia, in the bishopric of Osnabruck; 7 miles N.E. of Osnabruck.

*RUM*, a species of vinous spirit, drawn by distillation from sugar-canes.

The word rum is the name it bears among the native Americans.

Rum is very hot and inflammable, and is in the same use among the natives of the sugar-countries, as brandy among the French.

Rum differs from what we simply call sugar-spirit, in that it contains more of the natural flavour or essential oil of the sugar-cane; a great deal of raw juice, and parts of the cane itself, being often fermented in the liquor, or solution of which the rum is prepared.

The unctuous or oily flavour of rum is often supposed to proceed from the large quantity of fat used in boiling the sugar; which fat, indeed, of course, will usually give a stinking flavour to the spirit in our distillation of the sugar liquor, or wash, from our refining sugar-houses; but this is nothing like the flavour of the rum, which is really the effect of the natural flavour of the cane. The method of making rum is this:

When a sufficient stock of the materials is got together, they add water to them, and ferment them in the common method, though the fermentation is always carried on very slowly at first; because at the beginning of the season for making rum in the islands, they want yeast, or some other ferment, to make it work; but by degrees, after this, they procure a sufficient quantity of the ferment, which rises up as a head to the liquor in the operation, and thus they are able afterwards to ferment and make their rum with a great deal of expedition, and in large quantities.

When the wash is fully fermented, or to a due degree of acidity, the distillation is carried on in the common way, and the spirit is made up proof; though sometimes it is reduced to a much greater strength, nearly approaching to that of alcohol or spirit of wine, and is then called double-distilled rum. It might be easy to rectify the spirit, and bring it to much greater purity than we usually find it to be of; for it brings over in the distillation a very large quantity of the oil; and this is often so disagreeable, that the rum must be suffered to lie by a long time to mellow before it can be used; whereas, if well rectified, it would grow mellow much sooner, and would have a much less potent flavour.

The best state to keep rum in, both for exportation and other uses, is doubtless that of alcohol, or rectified spirit. In this manner it would be transparent in one-half the bulk it usually is, and might be let down to the common proof strength with water when necessary. For the common use of making punch, it would likewise serve much better in the state of alcohol; as the taste would be cleaner, and the strength might always be regulated to a much greater exactness than in the ordinary way.

The only use to which it would not serve so well in this state, would be the common practice of adulteration among our distillers; for when they want to mix a large portion of cheaper spirit with the rum, their business is to have it of the proof strength, and as full of the flavouring-oil as they can, that it may drown the flavour of the spirits they mix with it, and extend its own. If the business of rectifying rum was more nicely managed, it seems a very practicable scheme to throw out so much of the oil, as to have it in the fine light state of a clear spirit, but lightly impregnated with it; in this case it would very nearly resemble arrac, as is proved by the mixing a very small quantity of it with the tasteless spirit, in which case the whole bears a very near resemblance to arrac in flavour.

Rum is usually very much adulterated in England; some are so barefaced as to do it with malt-spirit; but when it is done with melasses-spirit, the tastes of both are so nearly allied, that it is not easily discovered. The best method of judging of it is by setting fire to a little of it; and, when it has burnt away all the inflammable part, examining the

phlegm both by the taste and smell. Shaw's Essay on Distillery.

Mr. B. Edwards, in his "History of the West Indies," vol. ii. has given the following account of the process for extracting rum from the sugar-cane, or from the very dregs and feculencies of the plant, by fermentation and distillation. He commences his account with observing, that the still-houses on the sugar-plantations in the British West Indies, vary greatly in point of size and expense, according to the fancy of the proprietor, or the magnitude of the property. In general, however, they are built in a substantial manner of stone, and are commonly equal to the boiling and curing-houses together. (See SUGAR.) For a plantation making, *communibus annis*, 200 hogsheds of sugar of 1600 weight, our author conceives, that two copper stills, the one of 1200, and the other of 600 gallons, wine measure, with proportionate pewter worms, are sufficient. The size of the tanks (or tubs) for containing the cold water in which the worms are immersed, must depend upon circumstances; if the advantage can be obtained of a running stream, the water may be kept abundantly cool in a vessel barely large enough to contain the worm. If the plantation has no other dependance than pond-water, a stone tank is much superior to a tub, as being longer in heating, and if it can be made to contain from twenty to thirty-thousand gallons, the worms of both the stills may be placed in the same body of water, and kept cool enough for condensing the spirit, by occasional supplies of fresh water.

For working these stills and worms, it is necessary to provide, first, a dunder-cistern, of at least three thousand gallons; secondly, a cistern for the scummings; and lastly, twelve fermenting vats, or cisterns, each of them of the contents of the largest still, *viz.* 1200 gallons. In Jamaica, cisterns are made of plank, fixed in clay; and are universally preferred to vats or moveable vessels, for the purpose of fermenting. They are not so easily affected by the changes of the weather, nor so liable to leak as vats, and they last much longer. But in the British distilleries, fermenting cisterns, it is said, are unknown. To complete the apparatus, it is necessary to add two or more copper pumps for conveying the liquor from the cisterns, and pumping up the dunder, and also butts or other vessels for securing the spirit when obtained; and it is usual to build a rum-store adjoining the still-house.

The ingredients or materials for the process consist of melasses, or treacle drained from the sugar; scummings of the hot cane-juice, from the boiling-house, or sometimes raw-cane liquor, from canes expressed for the purpose: lees, or, as it is called in Jamaica, "dunder," from the Spanish *redunder*, the same as *redundans* in Latin; and water. Dunder, in the making of rum, serves the purpose of yeast in the fermentation of flour. It is the lees or feculencies of former distillations; and some planters preserve it for use from one crop to another; but this is said to be a bad practice. Some fermented liquor, composed of sweets and water alone, ought to be distilled in the first instance, that fresh dunder may be obtained. This is a dissolvent menstruum, and occasions the sweets with which it is combined, whether melasses or scummings, to yield a far greater proportion of spirit than can be obtained without its assistance. The water which is added acts in some degree in the same manner by dilution.

In the Windward islands, the process, we are told, is conducted as follows: the ingredients, *viz.* scummings, one-third; lees or dunder, one-third, and one-third of water, are well mixed in the fermenting cisterns, and when they are pretty cool, the fermentation will rise, in twenty-four hours,

# RUM.

to a proper height for admitting the first charge of melasses, of which six gallons for every hundred gallons of the fermenting liquor, is the general proportion to be given at twice; *viz.* three *per cent.* at the first charge, and the other seven *per cent.* a day or two afterwards, when the liquor is in a high state of fermentation; the heat of which, however, should not, in general, be suffered to exceed from 90° to 94° Fahrenheit. The infusion of hot water will raise, and of cold water abate the fermentation. The quantity of melasses above-mentioned, added to a third of scummings, gives 11½ *per cent.* of sweets, six gallons of scummings being reckoned equal to one gallon of melasses. When the fermentation falls by easy degrees from the fifth to the seventh or eighth day, so as then to become fine, and throw up slowly a few clear beads or air-globules, it is ripe for distillation; though when the liquor is first set at the beginning of the crop (the house being cold, and the cisterns not saturated) it will not be fit for distillation under ten or twelve days. When this is the case, at a longer or shorter period, the liquor or wash being conveyed into the largest still, which must not be filled higher than within eight or ten inches of the brim, left the head should fly, a steady and regular fire must be kept up until it boils, after which a little fuel will serve. In about two hours the vapour or spirit, being condensed by the ambient fluid, will force its way through the worm in the shape of a stream, as clear and transparent as crystal, and it is suffered to run until it is no longer inflammable. The spirit thus obtained is known by the appellation of "low wines." To make it rum of the Jamaica proof, it undergoes a second distillation. Between the practice of the Jamaica distillers, and that of those of the Windward islands, there is some little variation in the first process. This consists chiefly in the more copious use of dunder. As dunder serves to dissolve the tenacity of the saccharine matter, it should be proportioned, not only to the quantity, but also to the nature of the sweets. If the sweets in the fermenting cistern consist of melasses alone, which is generally the case after the business of sugar-boiling is finished, when no scummings are to be had, a greater proportion of dunder is necessary; because melasses are a body of greater tenacity than cane-liquor, and are rendered so viscous and indurated by the action of fire, as to be unfit for fermentation without the most powerful saline and acid stimulators. For the same reason, at the beginning of the

crop, when no melasses can be had, and the sweets consist of cane-juice or scummings alone, very little dunder is necessary. In such case twenty *per cent.* at the utmost will be sufficient. Dunder, in a large quantity, injures the flavour, though it may increase the quantity of the spirit. Dr. Shaw says, that the English distillers add many things to the fermenting liquor or wash, in order to augment the vinosity of the spirit, or to give it a particular flavour. He observes, that a little tartar, nitre, or common salt, is sometimes thrown in at the beginning of the operation, or in their stead a little of the vegetable or finer mineral acid. These are thought to be of great use in the fermenting of solutions of treacle, honey, and similar sweet and rich vegetable juices, which contain a small proportion of acid. A similar practice is said to prevail among the distillers in St. Christopher's, some of which consider an addition of sea-water to the fermenting liquor as a real and great improvement. Shaw recommends the juice of Seville oranges, lemons, and tamarinds, or other very acid fruits, and, above all other things, an aqueous solution of tartar; but Mr. Edwards is of opinion, that dunder alone answers every purpose. Dr. Shaw also recommends to the distiller to introduce into the fermenting cistern a few gallons of the rectified spirit, which, he says, will revert, with a large addition, to the quantity of spirit that would otherwise have arisen from the distillation. It is suggested by Mr. Edwards, that a small quantity of vegetable ashes, thrown into the rum-still, will be found serviceable. The alkaline salts are supposed to attenuate the spirit, and keep back the gross and fetid oil, which the distillers call the "faints," but if too freely used, they will also keep back a proportion of the fine essential oil, on which the flavour of the rum wholly depends. After all, the most important object of attention in making good rum is probably "cleanliness;" for all adventitious or foreign substances destroy or change the peculiar flavour of the spirit. It should, indeed, be an invariable practice with the manager or distiller to take care that the cisterns are scalded, and even cleaned with strong lime-water, every time when they are used; not merely on account of the rum, but because it has often happened that the vapour of a foul cistern has instantly killed the first person that has entered it without due precaution.

The following improved method of conducting the process, or of compounding the several ingredients, is very general in Jamaica, *viz.*

Dunder one half, or	-	-	-	-	50 gallons	}	42 gallons.
Sweets 12 <i>per cent.</i>	{	Melasses	-	-	6 gallons		
		Scummings	-	-	36 gallons		
				(equal to six gallons more of melasses)			
Water	-	-	-	-	8 gallons		

100

Of this mixture, or "wash," as it is sometimes called, 1200 gallons ought to produce 300 gallons of low-wines; and the still may be twice charged or drawn off in one day. The method of adding all the melasses at once, which is done soon after the fermentation commences, renders the process safe and expeditious; whereas by charging the melasses at different times, the fermentation is checked, and the process delayed.

The low-wines obtained in the manner above described, are drawn off into a butt or vessel, and, as opportunity serves, are conveyed into the second still of 600 gallons, to undergo a further distillation. The steam begins to run in about an hour and a half, and will give, in the course of

the day, 220 gallons, or two puncheons, of oil-proof rum, *i. e.* of spirit in which olive oil will sink; and thus the manufacture, if so it may be called, is complete. There will remain in the still a considerable quantity of weaker spirit, commonly about 70 gallons, which is returned to the low-wine butt. Thus 220 gallons of proof-rum are made, in fact, from 530 gallons of low-wines, or about 113 of rum from 1200 of wash. By this process the Jamaica distiller may fill weekly, working only by day-light (a necessary precaution in this employment), and at a small expence of labour and fuel, twelve puncheons of rum, containing each 110 gallons of the Jamaica standard. The proportion of the whole rum to the crop of sugar, is commonly estimated

in Jamaica as three to four. Thus a plantation, such as we have above described, is supposed to supply annually 150 puncheons of rum of 110 gallons each, or 82 gallons of Jamaica proof to each hoghead of sugar; and this quantity is sometimes fairly made from canes planted in rich and moist lands; but on a general estimate, Mr. Edwards thinks this to be too great an allowance; and that 200 gallons of rum to three hogheads of sugar, which is in the proportion of about two-thirds rum to the crop of sugar, is nearer the truth. The following statement warrants the above conclusion. The general supply of scummings to the liquor-house is seven gallons out of every 100 gallons of cane-liquor. Supposing, therefore, that 2000 gallons of cane-juice are required for each hoghead of sugar of 16 cwt., the scummings, on a plantation making 200 hogheads *per annum*, will be 28,000 gallons, equal to 4666 gallons of melasses.

Add the melasses from the cur- ing-house, which, if the sugar is of a good quality, will sel- dom exceed 60 gallons <i>per</i> hoghead	}	12,000
--	---	--------

Total of sweets	16,666 gallons.
-----------------	-----------------

This quantity, distilled at or after the rate of 12 *per cent.* sweets in the fermenting cistern, will give 34,720 gallons of low-wines, which ought to produce 14,412 gallons of good proof rum, or 131 puncheons of 110 gallons each. When a greater proportion than this is made, either the sugar discharges an unusual quantity of melasses, or the boiling-house is defrauded of the cane-liquor by improper scumming; which latter circumstance frequently happens.

It is the practice of late, we are told, with many planters, to raise the proof of rum: thus gaining in strength of spirit what is lost in quantity: and some managers make it a rule to return the scummings to the clarifiers, instead of leading them to the still-house. This last-mentioned practice reduces the crop of rum more than one-third; but is supposed to yield in sugar more than is lost in rum: and if the price of sugar is very high, and that of rum very low, it may be prudent to adopt this method.

For the duty, &c. on rum, see *Foreign Spirits*.

RUM, in *Geography*, a town of Tonquin, on the coast. N. lat. 19° 35'. E. long. 105° 18'.—Also, a river of America, which runs into the Mississippi, N. lat. 45°. W. long. 93° 48'.

RUM, one of the Hebrides, or Western islands of Scotland, is situated to the westward of the isle of Skye, and is comprised, politically, in the parish of Small-Isles, and in the county of Argyle. It derived its name from the Gaelic, *Rhum*, signifying extent, in allusion to its being the largest island in the parish to which it belongs. It is computed to measure eight miles in length, and nearly the same in breadth; and to contain about 22,000 square acres. Rum is in general rugged, mountainous, and barren, and more adapted for pasturage than for agriculture. Horses are reared in this island for sale, and though diminutive in size, are remarkably high mettled and hardy. Here are likewise reared a considerable number of sheep, which are the best stock with which a mountainous country, like Rum, can be supplied. The general breed is a small white-faced sheep, which is much praised, both for the delicate flavour of its flesh, and for the excellence of its wool. This island formerly abounded with deer; but that animal is now totally extirpated, owing to the copse wood, which served as a cover to their fawn, having been destroyed. Before the use of fire-arms, the method adopted by the inhabitants to kill deer was so sin-

gular as to deserve notice. On each side of a glen formed by two mountains, stone dykes were constructed at a considerable height up the hills, and extended from thence to the lower part of the valley, always drawing nearer to each other, till they approached within three or four feet. This narrow pass opened into a circular space, inclosed by a wall of sufficient height to restrain the deer, which were pursued hither and destroyed. The remains of one of these ancient deer-traps are still to be traced. Birds of prey are numerous in Rum; and there are likewise a few grouse, pigeons, terrapants, and wild ducks, besides those birds which frequent the island only at stated seasons of the year. The air of Rum, from its proximity to the western ocean, is moist, and the weather extremely rainy. The only harbour here is Loch-Serefort, which penetrates a considerable way into the island, on its eastern coast. It is spacious, its ground good, and its depth of water from five to seven fathoms. Near the head, on the south side of this harbour, a pier has been lately erected. The general appearance of Rum is, that the land slopes towards the east; but on the west presents precipices of a tremendous height. At the base of the hill Sgarmor are found abundance of agates, of that species called by Cronstedt "Achates chalcidomifans," improperly white cornelians. Here are several remarkable strata; such as grey quartz; a mixture of quartz and basalt; a black stone spotted with white, like porphyry, but with the appearance of lava; fine grit or free-stone; and the cinereous indurated bole of Cronstedt. There being no mill in this island, the corn is "gradanned," or burnt out of the ear, instead of being thrashed. This is performed in two ways: first by cutting off the ears and drying them in a kiln, and then letting fire to them on the floor, and picking out the grains; and secondly, by burning the sheaf entire, which is a most ruinous practice, as it destroys both thatch and manure. Gradanned corn is conjectured to have been the parcelled corn of holy writ.

Rum not being a parish of itself, its population is not stated in the parliamentary returns; but it is estimated to contain about 500 inhabitants. The Statistical Account of Scotland, by Sir John Sinclair, bart. 8vo. vol. xvii. 1796. Beauties of Scotland, vol. v. 8vo. 1808. Carlisle's Topographical Dictionary, 4to. 1813.

RUM *Key*. See RONCADOUR.

RUMAHIE. See ROMAHIE.

RUMB, RUM, or *Rhumb*, in *Navigation*. See RHUMB.

RUMB-Line, or *Loxodromia*. See RHUMB-Line.

RUMBLE, in *Geography*, one of the smaller Shetland islands; two miles S. of Yell. N. lat. 60°. W. long. 0° 56'.

RUMBURG, a town of Bohemia, in the circle of Leitmeritz, in which are considerable manufactures of linen; nine miles N.E. of Kamnitz.

RUMEL, a town of Asiatic Turkey, in the province of Diarbekir; 30 miles E. of Nisbin.

RUMELY, a town of Syria, in the packalic of Tripoli, on the coast; 15 miles S. of Bairut. N. lat. 33° 33'. E. long. 35° 28'.

RUMEN, the first stomach of animals which chew the cud, and which are hence called *ruminants*.

The food is transmitted into the rumen without any other alteration in the mouth than being a little rolled and wrapped up together.

For an account of the rumen, see *Anatomy of MAMMALIA*.

RUMEX, in *Botany*, the Dock and Sorrel genus; named, as it seems, by the Latins themselves, from *rumex*, a sort of pike, spear, or halberd, which the shape of the leaves, in various

## RUMEX.

various species, much resembles. We cannot but prefer this etymology to that taken from *rumo*, to suck, by which the acid flavour of Sorrel, useful in allaying thirst, was supposed to be indicated.—Linn. Gen. 178. Schreb. 238. Willd. Sp. Pl. v. 2. 249. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 2. 318. Sm. Fl. Brit. 390. Prodr. Fl. Græc. Sibth. v. 1. 244. Brown Prodr. Nov. Holl. 421. Pursh 247. Juss. 82. Lamarck Illustr. t. 271. Gærtn. t. 119. (Lapathum; Tourn. Inst. 504. Acetosa; ibid. 502. t. 287.)—Clas and order, *Hexandria Trigynia*. Nat. Ord. *Holeraceæ*, Linn. *Polygonææ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of three obtuse, reflexed, permanent leaves. *Cor.* Petals three, ovate, similar to the calyx, but larger, converging, permanent, forming valves over the seed. *Stam.* Filaments six, capillary, very short; anthers erect, of two lobes. *Pist.* Germen superior, triangular, turbinate; styles three, capillary, reflexed, projecting between the petals; stigmas large, lacinated. *Peric.* none, the converging, triangular, hardened corolla, unfolding the seed. *Seed* solitary, triangular.

Ess. Ch. Calyx of three leaves. Petals three, converging, permanent. Seed solitary, triangular, superior, without a seed-vesicle. Stigmas many-cleft.

Obs. *R. digynus* excludes one-third in the number of every part of the fructification, except the Stamens. Those species which compose the Sorrel tribe, have flowers with stamens on one plant, flowers with pistils mostly on another, being dioecious, or in some instances monoecious. *R. spinosus* is monoecious; and the perianth of the female flowers becomes hooked and rigid. *R. alpinus* is polygamous. In several species the petals are distinguished by a tumid, hard, mostly coloured, grain, or roundish tubercle, at the back, most conspicuous when the seed ripens; sometimes of equal size in all, sometimes obsolete in two of the petals. This is a genus of hardy, perennial, almost invariably herbaceous plants, nearly allied to RHEUM; see that article. They have small pretensions to be considered as ornamental, and, on the contrary, are generally esteemed weeds, because they mostly grow where they are a nuisance and encumbrance. The agriculturist stigmatizes with the name of Docks, all large, biennial or perennial, strong-rooted, rank-growing herbs, and generally pays for their extirpation, according to a settled rate, under that denomination. The roots of the various species of *Rumex* are astringent; their herbage is likewise often so, though sometimes very acid. Every part of the plant is greenish, with a strong tendency to become red by age. Botanists differ about the denomination of the parts of the flower. Analogy and theory teach the whole of the integuments in this genus and *Rheum* to be a calyx; but the three inner divisions in *Rumex* having a separate insertion, somewhat of a different texture or structure, and being so remarkably altered, in most species, as the fruit ripens; while in such species as have, after flowering, an enlarged or hardened calyx these inner segments remain unchanged, never undergoing any alteration in concert with the three outer segments; all this evinces that nature is not always conformable to our rules. The genus *Rumex* therefore is one of those in which we are obliged to use our discretion, as to the denomination of the *calyx* and *corolla*, in spite of arbitrary and absolute principles.

The species in Willdenow amount to 36. They are in general well defined, but several are misunderstood, or given twice; so that we must exhibit as compendious a view as possible of the whole, having also some to add. Eleven are natives of Britain. The Hortus Kewensis enumerates 27, two of which do not occur in Willdenow. They are com-mo-nously disposed in three sections.

VOL. XXX.

SECT. 1. *Stamens and pistils in the same flowers. Valves distinguished by a granular tubercle.*

1. *R. Patientia*. Patience Dock or Rhubarb. Linn. Sp. Pl. 476. Willd. n. 1. Ait. n. 1. Ehrh. Pl. Off. n. 273. (Hippolapathum fativum; Ger. Em. 389. H. hortense; Matth. Valgr. v. 1. 407.)—Flowers united. Valves entire, ovate; one of them minutely granular. Leaves ovato-lanceolate, taper-pointed.—Native of Italy. Long cultivated in kitchen or rustic gardens, having been sometimes used as a pot-herb, and the root occasionally employed as a purgative medicine, in the place of Rhubarb. Hence it is sometimes called Monk's Rhubarb, though that name is now retained rather for the *Rumex alpinus*. The *Patientia* is four or five feet high, erect, smooth, green; its leaves from twelve to eighteen inches long, rather narrow. *Flowers* in whorled or tufted clusters, copious, pendulous. *Petals* large, ovate, reticulated with veins; the midrib of one of them swelling, in its lower part, into an oblong, not very evident, grain. We now rather prefer the above cut of Gerarde, to that of Dodonæus cited by Linneus.

2. *R. sanguineus*. Bloody-veined Dock. Linn. Sp. Pl. 476. Willd. n. 2. Ait. n. 2. Pursh n. 1. Fl. Brit. n. 1. Engl. Bot. t. 1533. (Lapathum fativum sanguineum; Ger. Em. 390.)

*β.* *R. acutus*; Curt. Lond. fasc. 3, 21, the description, not the figure. (*R. Nemolapathum*; Ehrh. Phytoph. n. 94. Linn. Suppl. 212. Bloodless Dock; Petiv. H. Brit. t. 2. f. 6.)—Flowers united. Valves entire, oblong; one of them chiefly granular. Leaves lanceolate, heart-shaped at the base.—Native of Europe, in woods and by way sides. Dr. Sibthorp found it in Greece, and though not very common in England, it occurs in various parts. Mr. Pursh says it grows in shady woods and moist meadows, from Pennsylvania to Virginia, flowering in June and July. The green variety, *β*, is very common in England, under the shade of trees in rather dry woods. Perhaps it ought to be esteemed the original species; the kind whose stalks and veins contain a crimson juice, being perhaps the variety. This last appears, by Gerarde's herbal, to have been first known here as a pot-herb. Linneus mentions Virginia only as its native country, and marks it as biennial. With us both varieties are certainly perennial. The plant is erect, three or four feet high, branched, rather slender, and of a delicate appearance. *Flowers* small, in long clusters of very numerous tufts or whorls; their petals oblong and obtuse, one of them bearing an extremely large, globular, red grain.

3. *R. spatulatus*. Spatulate Cape Dock. Thunb. Prodr. 67. Willd. n. 3.—“Leaves obovate, obtuse. Valves granular.”—Found by Thunberg at the Cape of Good Hope.

4. *R. crispus*. Curled Dock. Linn. Sp. Pl. 476. Willd. n. 7. Ait. n. 3. Pursh n. 2. Fl. Brit. n. 2. Engl. Bot. t. 1998. Curt. Lond. fasc. 2. t. 20. (Lapathum longifolium crispum; Munt. Brit. t. 104.)—Flowers united. Valves ovate, wavy, entire, all granular. Leaves lanceolate, undulated, acute.—In waste ground, pastures, and by way sides, common throughout Europe, as well as in North America, flowering in June and July, and accidentally throughout the summer. This is a very troublesome and unprofitable weed; readily distinguished, as a species, from all other English Docks, by the curved leaves, and large entire valves, each bearing an ovate grain. These are by accidental error termed *calyx-valves* in *English Botany*. The root is tap-shaped, yellowish. Stem two or three feet high, branched, nearly smooth to the touch. Leaves of a lightish green. Clusters rather long; leafy in their lower part.

5. *R. verticillatus*. Whorled American Dock. Linn. Sp.

Sp. Pl. 476. Willd. n. 4. Pursh n. 3.—Flowers united. Valves somewhat deltoid, entire, all granular. Leaves flat, lanceolate; with tubular, membranous sheaths embracing the stem. Clusters nearly leafless.—In rivulets and shady woods, from Canada to Virginia, flowering in July, perennial. *Pursh*. The stem is somewhat zigzag, ascending, angular and furrowed, smooth, invested above every leaf with a tubular, pale, membranous, intrafoliaceous *stipula*, or sheath, near an inch long. Leaves flat and even. Flowers twice the size of the last, with very large oblong grains, which are often wrinkled. The *petal* itself is also strongly marked with projecting reticulated veins.

6. *R. Britannica*. Virginian Water-Dock. Linn. Sp. Pl. 476. Willd. n. 5. Pursh n. 4.—Flowers united. Valves ovate, obtuse, all granular. Leaves flat, lanceolate; with scarcely any sheaths. Clusters paniced, leafless.—Near rivulets in Virginia and Carolina; perennial, flowering in June and July. *Pursh*. This is readily distinguished from the last, with which Linnæus sometimes negligently confounded it, notwithstanding his own clear definition. The want of the tubular sheathing *stipulas* is alone sufficient. The grains on the valves are, moreover, much smaller, and Mr. Pursh has well adverted to the paniced inflorescence, composed of numerous, lax, many-flowered clusters. The specific name *Britannica*, not *britannicus*, alludes to former controversies, of Muntingius and others, about what was the true *Herba Britannica*; but why this American plant should be so called, we know no good reason, nor is it worth while to examine which of the bad figures in the verbose and useless author last named, is most, or least, like our plant. None of them, we believe, is properly referrible to it. The *Herba Britannica* of the ancients is said to have been a powerful antiscorbutic, or tonic, and was found on our own, or the neighbouring, coasts.

7. *R. persicarioides*. Persicaria Dock. Linn. Sp. Pl. 477. Willd. n. 9. Ait. n. 4. Pursh n. 5.—Flowers united. Valves lanceolate, taper-pointed, toothed, all granular. Leaves lanceolate, wavy, nearly entire.—In shady wet woods, on the banks of ditches, in Virginia and Carolina, flowering in July, annual. Sent to Kew in 1773, by the chevalier Murray, professor at Gottingen, but we presume it is scarcely preserved, being so like our common docks, except the advantage, in this case, of having only an annual root. The clusters are accompanied, at each whorl, with a stalked leaf, rather smaller than those on other parts of the branched stem. Flowers small, erect. Valves narrow, with long slender points, and each bearing a large, oblong, slightly kidney-shaped, smooth, tawny grain.

8. *R. crispatus*. Crisped Dock. Michaux Boreali-Amér. v. 1. 217. Pursh n. 6.—Flowers united. Valves heart-shaped, obtuse, three-toothed at each side; two of them granular. Clusters leafless. Leaves crisped and wavy at the margin; the lower ones oval; upper lanceolate.—Native of Kentucky. *Michaux*. Akin to the last. Its habit is said to be like *R. acutus*, but the valves investing the seed are much larger. One of them bears no granular tubercle, and the grains of the two others are unequal in size. The upper leaves are minutely crenulated.

9. *R. ægyptiacus*. Egyptian Dock. Linn. Sp. Pl. 477. Willd. n. 10. Ait. n. 5. (*Lapathum ægyptium* annum, parietariæ folio, capsulâ feminis longiùs barbata; Till. Pif. 93. t. 37. f. 1.)—Flowers united. Valves with three very long capillary points at each side; one only bearing an ovate grain. Gathered near Memphis, by J. B. de Georgis, surgeon to the grand duke of Tuscany, whence it was introduced into the garden at Pisa, and soon after, as it appears, sent to Miller at Chelsea. The root is an-

ual. This species is readily known by the fine capillary teeth of its valves, spreading in every direction, and giving the clusters, which are long, dense, and leafy, a hairy appearance. Each valve is small, reticulated with strong veins.

10. *R. dentatus*. Sharp-toothed Dock. Linn. Mant. 226. Syft. Veg. ed. 13. 284. Willd. n. 11. Ait. n. 6. (*Lapathum ægyptium*, capsulâ feminis albâ et crenatâ; Boerh. Ind. Alt. v. 2. 85. Dill. Elth. 191. t. 158. f. 191.)—Flowers united. Valves with awl-shaped teeth; all granular. Clusters dense, leafy. Leaves lanceolate.—Gathered in Egypt, by the unfortunate Augustin Lippi, afterwards murdered by the barbarians of Nubia. This plant was originally confounded, by Linnæus, with the last, from which it differs essentially, having valves thrice as large, bordered with awl-shaped teeth, scarcely exceeding their own length, each valve bearing a large, pale, ovate grain.—The plant is annual, a span high, branched from the bottom.

11. *R. maritimus*. Golden Dock. Linn. Sp. Pl. 478. Willd. n. 12. Ait. n. 7. Fl. Brit. n. 6. Engl. Bot. t. 725. (*Lapathum anthoxanthum*; Baul. Hist. v. 2. 987.)—Flowers united. Valves deltoid, with setaceous teeth; each bearing a nearly cylindrical grain. Clusters dense. Leaves linear.—Native of marshes in various parts of Europe, chiefly near the sea. It is perennial, flowering in July and August. This is most akin to *R. ægyptiacus*, with which its dense leafy clusters, and tawny or golden hue, agree. But the foliage is more linear, and the teeth of the valves, though almost capillary, not one-third so long, while the valves themselves are larger, and every one of them marked with a grain, which is oblong, and nearly cylindrical, not ovate. The stem is strongly angular and furrowed, roughish, reddish, a little zigzag. Leaves stalked, bluntish, flat. Whorls very dense, and crowded into cylindrical leafy clusters, often of a rich golden hue. Seed very small, compared with our common docks.

12. *R. palustris*. Yellow Marsh Dock. Fl. Brit. n. 7. Engl. Bot. t. 1932. Ait. n. 8. (*R. maritimus*; Ehrh. Herb. n. 74. Curt. Lond. fasc. 3. t. 23. *Lapathum aquaticum*, luteolæ folio; Bocc. Mus. v. 2. 143. t. 104. *Hydrolapathum minus*; Lob. Ic. 286. Ger. Em. 309.)—Flowers united. Valves lanceolate, toothed at the base; each bearing an oblong grain. Leaves linear-lanceolate. Whorls distant.—Native of marshes, ditches, and wet waste places in Germany, Italy, and England. Found in several situations near London; also at Acle and Saham in Norfolk. It is perennial, flowering in July and August. Many botanists have confounded this with the last, from which it differs in having distant leafy whorls, and lanceolate valves, each furnished at the base, on each side, with three slender teeth, much shorter than the foregoing. The leaves are linear-lanceolate and acute; the radical ones very large. Stem furrowed, reddish, rough to the touch. The root, as Curtis observed, is red internally.

13. *R. divaricatus*. Spreading Italian Dock. Linn. Sp. Pl. 478. Willd. n. 13. Ait. n. 10. (*Lapathum arvense subhirsutum*, folio retuso, caule longiùs brachiato, capsulâ feminis crenatâ; Till. Pif. 93. t. 37. f. 2.)—Flowers united. Valves heart-shaped, toothed, granular. Leaves heart-shaped-oblong, obtuse, downy.—Native of fields in Italy. Root annual. Linnæus truly says, that Haller considered this as the same with *R. pulcher* hereafter described. We have seen no specimen; but though in Tilli's figure the valves investing the seed are not very unlike those of *pulcher*, the large oblong leaf, not at all contracted in the middle, and hairy as well as its footstalk, has

## RUMEX.

has a very different appearance. Moreover, this species is cultivated at Kew, where it was introduced in 1793, by Mr. Hunnemann, and is published by Mr. Aiton as distinct. It flowers in July and August. See *R. auratus*, n. 30.

14. *R. acutus*. Sharp Dock. Linn. Sp. Pl. 478. Willd. n. 14? Ait. n. 11. Fl. Brit. n. 3. Engl. Bot. t. 724.

*β*. *Lapathum acutum minimum*; Dill. in Raii Syn. 141. Bauh. Hist. v. 2. 985. (Small Sharp Dock; Petiv. H. Brit. t. 2. f. 4.)—Flowers united. Valves oblong, obscurely toothed, each bearing a roundish prominent grain. Leaves oblong, pointed; somewhat heart-shaped at the base. Clusters leafy.—Native of marshy meadows in England, and other parts of Europe, perennial, flowering in July. The *stem* is erect, or somewhat zigzag, angular, furrowed, smooth to the touch. *Leaves* narrow; the lower ones only slightly heart-shaped; all smooth and flat. *Branches* elongated into long spreading *clusters*, consisting of numerous, distinct, and rather distant, *whorls*, each of which is accompanied by a small, lanceolate, stalked leaf. The *flowers* are occasionally polygamous, and some of the males have been observed by Mr. Sowerby to be furnished with twelve *stamens*; the greater part of the flowers however have usually six only, in the same calyx with the pistil. The *seed* is small. *Valves* oblong and bluntish, mostly entire, though sometimes toothed at the base, each of them bearing a large, red, almost globular, *grain*, of the same size in all.

This is a species about which there has been more doubt and controversy than any other. Most botanists have mistaken for it our green variety of *R. sanguineus*, n. 2, and we can by no means be certain how far Mr. Curtis has committed the same error. The two plants however are perfectly distinct, nor is there any uncertainty in the characters by which we have defined them. The present has a large grain on each *valve*, and the *whorls* are most of them, if not all, accompanied by a leaf. The other has two of the *valves* without grains, the third bearing a very large one, and there is only a leaf or two, here and there, at the lower whorls; the long series of them above being leafless. By an attention to this last character, the figures of old authors, bad as they are, may be determined. With respect to Mr. Curtis's fine plate, we confess we remain in uncertainty. His *clusters* are almost leafless, like the *sanguineus β*, but his separate *flowers* unquestionably belong to the *acutus*. We have no doubt that he confounded these species, and that his expression of two of the *valves* being "generally naked," is calculated to square with both. Two of them are really in *sanguineus* always naked, nor do we find any uncertainty in this character.

15. *R. obtusifolius*. Broad-leaved Dock. Linn. Sp. Pl. 478. Willd. n. 15. Ait. n. 12. Pursh n. 7. Fl. Brit. n. 4. Engl. Bot. t. 1999. Curt. Lond. fasc. 3. t. 22. (*L. sylvestre, folio minus acuto*; Ger. Em. 388. Lob. Ic. 285.)—Flowers united. Valves toothed; one principally grained. Radical leaves heart-shaped, obtuse. Stem roughish.—A common and troublesome weed throughout Europe, flowering in July and August. The long, perennial tap *root* runs deep into the ground, and is yellowish, not red, within. *Stems* numerous, two or three feet high, furrowed; roughest in the upper part. Radical *leaves* very large and spreading; wavy, more or less blunt, not unlike those of horse-radish, but hardly so big; their *footstalks* long and channelled. Stem *leaves* much narrower and more pointed, on shorter stalks, somewhat crisped and crenate. *Clusters*

generally bearing a few leaves, though often destitute of any. *Seed* large. *Valves* rather large, oblong-heart-shaped, entire at the extremity, but having three sharp prominent teeth near the base. The outermost bears an oblong *grain*, smaller in proportion to the valve than in most of the foregoing, and the grains of the two other valves are hardly discernible.

Mr. Curtis recommends frequent mowing as a sure means of destroying this dock. Mr. Pursh speaks of it as a common weed in old pastures and gardens in North America, though probably introduced from Europe.

16. *R. pulcher*. Fiddle Dock. Linn. Sp. Pl. 477. Willd. n. 16. Ait. n. 13. Fl. Brit. n. 5. Engl. Bot. t. 1576. (*Lapathum pulchrum bononiense sinuatum*; Bauh. Hist. v. 2. 988. Fiddle Dock; Petiv. H. Brit. t. 2. f. 10.)—Flowers united. Valves many-toothed; one of them bearing a larger grain than the rest. Radical leaves fiddle-shaped. Stem smooth, straggling.—Native of dry gravelly pastures, and waste ground, in the more temperate parts of Europe, from England to Greece; perennial, flowering in August. The radical *leaves*, so remarkably contracted in one part as to resemble a fiddle; the widely spreading, almost horizontal, *stems* and *branches*; and the sharp numerous teeth of the strongly reticulated *valves*, clearly mark this species. The outer *valve* bears an oblong reddish grain, larger than what usually occurs on the others. *Seed* very smooth and polished, with thin acute angles. A small leaf accompanies each *whorl*, though sometimes scarcely longer than the *flower*. The *petals* are larger and more coloured in some Swiss specimens, than we have noticed them in the flowering state of our English plants. Willdenow repeats under this species the synonym of Tilli, which properly belongs to *R. divaricatus*; apparently on the authority of Willich. See our remarks under n. 13.

17. *R. aquaticus*. Great Water Dock. Linn. Sp. Pl. 479. Willd. n. 18. Ait. n. 9. Pursh n. 8. Fl. Brit. n. 8. Engl. Bot. t. 2104. Ehrh. Pl. Off. n. 114. (*R. Hydrolapathum*; Hudf. 154. Willd. n. 6. Woodv. Med. Bot. t. 178. *R. acutus*; Ehrh. Pl. Off. n. 104. *Lapathum*, n. 1588; Hall. Hist. v. 2. 271. *Hydrolapathum magnum*; Lob. Ic. 285. Ger. Em. 389.)—Flowers united. Valves ovate, almost entire, bearing small or obsolete grains. Leaves lanceolate, acute; the lower ones heart-shaped at the base.—Native of ditches, pools, and the borders of rivers, throughout Europe; as well as in North America, from Pennsylvania to Virginia, but, according to Mr. Pursh, not common. With us it is very plentiful and conspicuous, being by far the largest of our docks, and flowering in July and August.—The *root* is large, knobby, and perennial. *Stems* erect, four or five feet high, angular, and strongly furrowed. *Leaves* a foot long, (more or less,) coriaceous, smooth, with a glaucous hue, entire, sometimes minutely curled at the edge. *Clusters* branched, dense, mostly leafless. *Flowers* numerous, on slender drooping stalks. *Valves* ovate, veiny, entire, or very sparingly notched, each bearing an ovate grain, various in size, or sometimes having only a tumid rib. The former is usually the case with our British plant, and is conspicuous in Ehrhart's Pl. Off. n. 114, which he gives as *R. aquaticus* of Linnæus from Upsal; while his n. 104, without grains, is marked, certainly erroneously, *acutus* of Linnæus, and is likewise from Upsal. The authentic Swedish specimen, in the Linnæan herbarium, precisely resembles the first of these in habit, while its valves, having scarcely any indications of grains, agree with those of the latter. We believe the presence or absence of grains, in this case, does not afford a specific difference. Hence, however, it readily appears

why authors have been led to describe the same plant twice, and to confound its synonyms.

Sect. 2. *Stamens and pistils in the same flowers. Valves naked, or without grains.*

18. *R. bucephalophorus*. Basil-leaved Dock. Linn. Sp. Pl. 479. Willd. n. 17. Ait. n. 14. Cavan. Ic. v. 1. 31. t. 41. f. 1. Sm. Fl. Græc. Sibth. t. 345, unpublished. (*Acetosa ocimi folio neapolitana βυκεφαλοφωρα*; Column. Ephr. part 1. 151. t. 150.)—Flowers united. Valves naked, veinless, with hooked teeth. Flower-stalks ternate, roughish; dilated and vaulted when in fruit.—Native of Italy, Barbary, and the Levant. Common in spring in the corn-fields of Greece and the neighbouring islands, according to Dr. Sibthorp, who judged it to be *λαπαθον το μικρον* of Dioscorides. It is annual, and has been occasionally raised in our gardens for near 150 years past, for the sake of its curious and singular structure. The root is fibrous. *Herb* very variable in luxuriance; sometimes simple, two or three inches high; sometimes branched from the base into several ascending, leafy, simple stems, flowering almost all the way up. *Leaves* stalked, ovate, or spatulate, smooth, entire. *Stipulas* membranous, white, long, and taper-pointed. *Flowers* always three together, in a series of whorls, partly axillary, but chiefly leafless. *Flower-stalks* deflexed, red, roughish with minute granulations, as well as the tawny or reddish calyx and petals. The latter are three-lobed, and become ovate pointed valves, each beset at the margin, on each side, with about three awl-shaped, hooked teeth or spines. As the fruit advances, each flower-stalk becomes lengthened, and dilated towards the calyx, being convex above, and vaulted underneath, not properly, as Linnæus says, “plane,” neither is it tumid or club-shaped. Columna, by a stretch of fancy, compares the valves in fruit to a bull’s head, two segments of the reflexed calyx looking like horns.

19. *R. fimbriatus*. Fringed New Holland Dock. Brown n. 1.—“Flowers united. Valves naked, veiny, fringed with hooked teeth. Flower-stalks reflexed and thickened when in fruit.”—Gathered by Mr. Brown, near Port Jackson, New South Wales. We have seen no specimen. This species seems very nearly akin to the last.

20. *R. vesicarius*. Bladder Dock, or Sorrel. Linn. Sp. Pl. 479. Willd. n. 20. Ait. n. 16. (*Acetosa americana, foliis longissimis pediculis donatis*; Bauh. Prodr. 54. Morif. sect. 5. t. 28. f. 7. *A. vesicaria peregrina*; Besl. Hort. Eyst. vern. ord. 6. t. 15. f. 3.)—Flowers united. Stalks mostly in pair. All the valves very large, membranous, entire, folded back. Leaves undivided.—Native of Africa. A hardy annual in our gardens, where it appears to have been first cultivated by Tradescant, in 1656. It flowers in July and August. The stem is branched, from a span to 18 inches high, smooth. Leaves on long stalks, ovate and obtuse, but with two angles at the base, so as to approach a halberd-shape. The plant is chiefly remarkable for the beauty of its large shining membranous valves, reticulated with veins, and tinged with a light rose-colour. These invest the ripe seed, hanging on capillary drooping stalks in great abundance. The figure in the *Hortus Eyskelensis* is much the best, were it not so difficult of access, on account of the unweildiness, and bad arrangement, of that pompous old book.

21. *R. roseus*. Rose-coloured Dock. Linn. Sp. Pl. 480. Willd. n. 21. Ait. n. 17. Sm. Fl. Græc. Sibth. t. 346, unpublished. (*Acetosa ægyptia, roseo feminis involucro, folio lacero Lippi*; Shaw Specim. n. 5. t. 1?)—Flowers united. Valves unequal, membranous, rounded, reticulated, toothed. Leaves undivided.—Native, as it is

said, of Egypt. Dr. Sibthorp found it in the isle of Cyprus, and his fine figure is the only good one we have met with; for the miserable sketch of Shaw appears certainly to have been taken from the *tingitanus*, with whose leaves it accords, though not with those of *roseus*; yet from this plate it seems Linnæus borrowed a part of his character, “*foliis erosis*,” which does not agree even with his own poor specimen. The true *roseus*, from a simple annual root, throws up several spreading, ascending, leafy stems, near a span high. Leaves on long stalks, undivided, entire, of an oblong, slightly hastate figure, but much narrower than in the last species. The whole herb is roughish, with a sort of hoary mealiness. Flowers, as well as their stalks, and the valves investing the seed, of an elegant rose-colour; the lobes of the valves semi-orbicular, membranous, strongly reticulated with red veins, and bordered with fine sharp teeth.

22. *R. tingitanus*. Tangier Dock. Linn. Sp. Pl. 479. Willd. n. 22. Ait. n. 18. (*Acetosa dentata perpetua di Tanger*; Zanon. Ist. 14. t. 5. (*Lapathum maritimum scetidum*; Bauh. Prodr. 56.)—Flowers united. Valves heart-shaped, obtuse, membranous, entire. Leaves hastate, ovate, jagged.—Native of Barbary, Spain, and Cyprus. Hardy in our gardens, flowering from June to August.—Root perennial, creeping. Stems about a foot high, ascending, branched. Leaves on long stalks, roughish, consisting of a large, ovate, acute, central lobe, with two small transverse ones at the base; all crisped or jagged at the edges, sometimes pinnatifid. Flowers in long clusters, two or three together, with a membranous bractea under them. Valves not half the size of the two last, whitish and shining. Shaw’s figure, cited under *roseus*, exactly represents this species, and we find Desfontaines has removed it hither.

23. *R. scutatus*. French, or Garden, Sorrel. Linn. Sp. Pl. 480. Willd. n. 23. Ait. n. 19. (*Acetosa rotundifolia hortensis*; Morif. sect. 5. t. 28. f. 9. *Oxalis franca fœu romana*; Ger. Em. 397.)—Flowers united. Leaves hastate, somewhat heart-shaped. Stem round. Native of Switzerland, the south of France, and some parts of Germany, in stony places. Cultivated for the use of the table, in every kitchen-garden, since the days of Gerarde. It is a perennial herb, flowering in June and July. The leaves are very smooth and rather glaucous, quite entire, supported by long stalks. Their flavour is very gratefully acid, either recent or stewed. Flowers small, racemose, pendulous. Valves orbicular, entire.

*R. glaucus*, Jacq. Ic. Rar. t. 67, is a more glaucous and small-leaved variety, whose stem is said to be in some degree woody.

24. *R. nervosus*. Three-ribbed Dock. Vahl. Symb. v. 1. 27. Willd. n. 24. (*R. perficarioides*; Forsk. Ægypt. Arab. 76.)—Flowers united. Valves orbicular, entire, naked. Leaves oblong, three-ribbed. Gathered by Forskall, on the mountains of Hadi, in Arabia. The stem is rather shrubby, with round striated branches. Leaves stalked, oblong; the uppermost lanceolate; all of them acute, entire, fleshy, very smooth, glaucous, an inch or more in length, with three ribs, but no veins. Stipulas membranous, sheathing, abrupt. Panicle terminal. Flower-stalks capillary, thickened under the flower, longer than the fruit. Calyx reflexed. Valves orbicular, smooth, without grains. Vahl.

25. *R. digynus*. Mountain Sorrel. Linn. Sp. Pl. 480. Willd. n. 25. Ait. n. 20. Pursh n. 9. Fl. Brit. n. 9. Engl. Bot. t. 910. Fl. Dan. t. 14. (Welsh Sorrel; Petiv. H. Brit. t. 3. f. 4.)—Flowers united. Styles two. Valves ovate, entire, naked. Leaves broadly emarginate.—Native of Alpine rivulets, on the mountains of Lapland, Labradore,

## RUMEX.

Labradore, Siberia, Switzerland, Wales, Scotland, and the north of England, always in very elevated spots, at least in our island, flowering in June. The *leaves* are nearly all radical, on long stalks, kidney-shaped, an inch wide, wavy, veiny, pale green, acid, each terminating in a broad shallow notch. *Stem* a span high, paniced. *Flower-stalks* in small groups or tufts, capillary. *Valves* ovate, emarginate, entire, reddish, with no traces of *grains*. The *flowers*, having but two *styles*, afford a decisive specific character of themselves, as well as an excellent name. The segments of the *calyx* are but two, as well as the *petals*, or *valves*. The *seed* is orbicular and flattish, having a broad border.

26. *R. lanceolatus*. Lanceolate Cape Dock. Thunb. Prodr. 67. Willd. n. 26.—“Leaves lanceolate, with a reflexed border. Stem angular.”—Found by Thunberg at the Cape of Good Hope. We have never seen it.

27. *R. graminifolius*. Grass-leaved Sorrel.—Leaves linear, entire, very narrow. *Stipulas* sheathing, imbricated. Panicle angular.—Native of Siberia. Communicated by professor Rudolph to A. B. Lambert, esq. under the above name, which very aptly describes the numerous, long, grassy *leaves*. The *stem* seems shrubby. *Flowers* small, in a forked racemose *panicle*. Our specimen is not perfect enough to shew whether the *stamens* and *pistils* are in the same *flower* or not, neither are the *valves* discernible. We therefore merely mention here, for further enquiry, this very curious and distinct species, of which we find no published account.

Sect. 3. *Perfect stamens and pistils in separate flowers.*

28. *R. Lunaria*. Tree Sorrel. Linn. Sp. Pl. 479. Willd. n. 19. Ait. n. 15. (*R. polygamus*; Cavan. Ic. v. 1. 14. t. 22. *Acetosa arborescens, subrotundo folio*; Pluk. Almag. 8. Phyt. t. 252. f. 3.)—Flowers monoecious. Males with twelve *stamens*. Anthers oblong. Females with six abortive ones. *Valves* rounded, granular. Stem shrubby. Leaves slightly heart-shaped.—Native of the Canary islands, from whence it was brought into the English green-houses, as soon as tender exotics became much cultivated. It flowers in June and July. The *stem* is shrubby, branched, spreading, often reddish. *Leaves* alternate, on longish stalks, fleshy, entire, smooth, of a pale glaucous hue and acid taste. *Stipulas* sheathing, broad, membranous, whitish. *Flowers* in a large, terminal, branched, racemose *panicle*; their particular structure Cavanilles first explained, and we have nearly verified his description. He knew not that his was a Linnæan plant, nor did the editors of Hort. Kew. discover his synonym. Some *flowers* are entirely male, with a three-cleft *calyx*, three very minute unchangeable *petals*, and twelve *stamens*, whose *anthers* are divided half way down. Other *flowers*, in the same *panicle*, have a similar *calyx* and *petals*, but the latter are subsequently enlarged into three orbicular, emarginate, veiny *valves*, each bearing a small *grain*. These flowers have mostly the rudiments of six *stamens*, but entirely ineffectual, hardly visible to the naked eye. We presume the large capillary tufts, described by Cavanilles, are the real *stigmas*, the *styles* being bent down to the bottom of the flower, as in many other species, with whose *stigmas* these plumose tufts exactly accord. But this we have not ascertained, as yet, in the living plant. Considering the present species as in fact monoecious, not polygamous, we have removed it to this section.

29. *R. hastulatus*. Little-halberd-leaved Sorrel.—Flowers separated, dioecious? Anthers orbicular. Stem shrubby, angular. Leaves halberd-shaped, revolute. Gathered by Mr. Menzies in Chili. The *stem* is woody, with numerous,

long, lax, zigzag, angular *branches*. *Leaves* half an inch long, or rather more, entire, minutely roughish, obtuse, tapering at the base into a *footstalk*, about half their own length. *Stipulas* short, membranous, obtuse. *Flowers* in solitary, terminal *clusters*, with a concave, thick, permanent *bractea*, and several minute membranous ones, under each little assemblage of three partial stalks. Segments of the *calyx*, as well as the *petals*, concave, reflexed. *Stamens* six, shorter than the *calyx*. *Anthers* of two round lobes, opening externally. We can discover no other than male flowers.

30. *R. auratus*. Golden-flowered Dock. (Favrodine dorée; Reynier Mém. de la Société de Lausanne, v. 2.)—Flowers separated, dioecious? *Stamens* nine or twelve. Anthers oblong. *Petals* none in the male. Stem herbaceous, angular. Leaves ovato-lanceolate, somewhat crenate, with hairy ribs.—Native of Switzerland. *Reynier, Davall*. First found by M. Favrod, in a meadow not far from the village of Castrod. M. Reynier, who conceived this plant to form a distinct genus from *Rumex*, on account of the want of *petals*, and the super-abundance of *stamens*, named it as above. His own specimen, now in our hands, and those of Mr. Davall, are entirely male. We have never seen either female flowers, or *fruit*; nor can we find any indication of this *Rumex* in Haller, or elsewhere. The *habit* of the herb bears a general resemblance to our common Docks, *acutus, crispus, &c.* The *stem* is angular, and strongly furrowed, paniced above, with long leafless *clusters* of innumerable small male *flowers*, of a green and tawny hue, on drooping capillary *stalks*. The *leaves* are lanceolate, ovate, or somewhat heart-shaped; their ribs, veins, and long *footstalks*, hairy. This last character induces a suspicion that the plant before us may possibly be the male of *R. divaricatus*, n. 13, a species concerning which very little is known, and which Haller, on the authority of Willich, reports to have, on cultivation, become the same as *pulcher*. Our *auratus* indeed is distinct from *pulcher*, but may be a variety of *divaricatus*, become occasionally dioecious, if it be not always so. The three segments of the *calyx* are spreading, linear, keeled and channelled, rather shorter than the *anthers*, which are cloven at the top.

31. *R. alpinus*. Alpine Dock, or Monk's Rhubarb. Linn. Sp. Pl. 480. Willd. n. 27. Ait. n. 21. (*Lapathum folio rotundo, alpinum*; Bauh. Hist. v. 2. 987. *Hippolapathum rotundifolium*; Ger. Em. 389.)—Flowers monoecious, or polygamous. *Valves* entire, naked. Leaves heart-shaped, obtuse, rugose.—Native of the alps of Switzerland, France, and Savoy, as well as of Greece and the Bithynian Olympus, flowering in July. Cultivated ever since Gerarde's time in our gardens, where it thrives, even in the smoke of London, and makes a very handsome appearance with its ample rich-green foliage. The *root* is thick, certainly perennial, though Linnæus and Willdenow mark it as biennial, and is said to possess the medical virtues of Rhubarb, in a weaker degree. *Footstalks* very long. *Stipulas* membranous, sheathing. *Stem* two feet high, erect, leafy, round, furrowed, smooth. *Clusters* forming an oblong, dense, leafy *panicle*, of innumerable green *flowers*, some of which have *stamens* with a, usually imperfect, *germen*; others are entirely female. *Valves* heart-shaped, strongly reticulated with veins; their midrib a little tumid, but not granular. *Seed* small.

32. *R. spinosus*. Prickly-seeded Dock. Linn. Sp. Pl. 481. Willd. n. 28. Ait. n. 22. Sm. Fl. Græc. Sibth. t. 347, unpublished. (*Beta cretica, femine aculeato*; Bauh. Prodr. 57. *B. cretica, femine spinoso*; Bauh. Hist. v. 2. 963.)—Flowers monoecious. *Calyx* of the females of one leaf

leaf, pitcher-shaped, with three spreading spinous points. Stem decumbent. Leaves slightly hastate.—Native of Gibraltar, Zante, Crete, and the neighbourhood of Athens; also of the Cape of Good Hope; cultivated here in 1656, by Tradescant. This is a prostrate, annual, widely spreading, and rank-growing herb, with the aspect and green hue of some kind of Beet. The *branches* are zigzag, round, striated. *Leaves* stalked, spreading, about two inches long and one broad, entire and smooth. Tufts of female *flowers* sessile, axillary; those of the males much fewer, leafless, about the ends of the branches, stalked and drooping. *Calyx* and *petals* of the latter alike, concave, obtuse, equal. *Stamens* six. *Calyx* of the former triangular, with six ribs, and curious depressions between; the three segments spreading, heart-shaped, folded, spinous-pointed, finally very hard and rigid. *Petal*: small, oblong, triangular, erect, permanent, but scarcely enlarged, the body of the *calyx* enclosing the *seed*. This singular species, in its *fruit*, as well as habit, approaches the nature of *Beta* and *Spinacia*.

33. *R. giganteus*. Tall Dock. Ait. n. 23.—“Flowers monoecious. Valves naked. Leaves oblong-ovate.”—Native of the Sandwich islands, from whence it was brought by Mr. Menzies, in 1796. It is a perennial green-house plant, flowering from June to August. Aiton.

34. *R. tuberosus*. Tuberous-rooted Dock. Linn. Sp. Pl. 481. Willd. n. 29. Ait. n. 24. Sm. Fl. Græc. Sibth. t. 348, unpublished. (*Oxalis tuberosa radice*; Bauh. Hist. v. 2. 991. Ger. Em. 396.)—Flowers dioecious. Valves naked. Leaves oblong-arrow-shaped; their lobes spreading. Root with oval knobs.—Native of Italy, Asia minor, and the islands of Cyprus and Lemnos. Miller is said to have cultivated this species, but it seems now lost. The *root* is perennial, with oval or oblong knobs, like those of *Spiræa Filipendula*. *Stems* a foot high. *Leaves* entire, with two divaricated lobes or points at the base, smooth. *Clusters* paniced, of an elegant rose-colour, especially when ripening *seed*. *Anthers* orange. *Stigmas* pink. *Valves* orbicular, obtuse; heart-shaped at the base, without *grains*.

35. *R. Acetosa*. Common Sorrel. Linn. Sp. Pl. 481. Willd. n. 31, excluding the last variety. Ait. n. 25. Fl. Brit. n. 10. Engl. Bot. t. 127. Woodv. Med. Bot. t. 69. (*Oxalis*, five *Acetosa*; Ger. Em. 396.)—Flowers dioecious. Valves granular. Leaves oblong-awl-shaped; their lobes converging, often notched.—Native of grassy pastures throughout Europe, from the alps of Lapland to Greece, flowering early in June. The *root* is perennial, tapering, running deep into the ground, tufted at the top, and throwing up several *stems*, one to two feet high, round, simple, leafy, striated. *Leaves* deep green, paler beneath; the lower and radical ones stalked; the upper sessile, somewhat revolute, clasping the stem; the points at the base of all rather directed inward than otherwise, and not in any degree divaricated; their edges nearly entire, or slightly crisped. *Stipulas* long, tubular, jagged at the summit. *Clusters* compound or aggregate, whorled, reddish. *Flowers* drooping, completely dioecious. *Petals* in both oblong-ovate, larger than the *calyx*, which latter is reflexed when in fruit. *Valves* ovate, obtuse, entire, each bearing an ovate *grain*. Linnæus in Fl. Lapp. ed. 2. 99, and Dillenius in Raii Syn. ed. 3. 143, mention a large alpine variety, for which the former cites Muntingius, (*de vera herba Britannica*;) *Acetola Hispanica maxima*, 225. t. 213. This author's plant seems rather the *arifolius* hereafter described, which we can scarcely believe to have been found either in Lapland or Merionethshire. *R. Acetosa* tastes gratefully acid, with a pleasant and wholesome astringency. It is, ac-

ording to Linnæus, much used by the Laplanders for preparing a kind of whey from rein-deer's milk, which will keep a long time, and is in great request among people of all ages.

36. *R. Acetofella*. Sheep's Sorrel. Linn. Sp. Pl. 481. Willd. n. 32. Ait. n. 26. Pursh n. 10. Fl. Brit. n. 11. Engl. Bot. t. 1674. Curt. Lond. fasc. 5. t. 29. (*Oxalis tenuifolia*; Ger. Em. 397. O. five *Acetosa*, minor; Matth. Valgr. v. 1. 406.)—Flowers dioecious. Valves naked. Leaves lanceolate-hastate.—Native of barren sandy or gravelly pastures and fields, throughout Europe, flowering in June and July. This is but half the size of the last, more slender in every part, and more of a red or tawny colour. The *root* is perennial and creeping. *Leaves* numerous; the radical ones hastate, their transverse lobes spreading at right angles with the central lobe, narrow and entire; stem-leaves often undivided. *Clusters* paniced, numerous. *Valves* ovate, nearly entire, all destitute of *grains*. The herb is acid.

37. *R. multifidus*. Many-cleft Sorrel. Linn. Sp. Pl. 482. Willd. n. 30. Sm. Fl. Græc. Sibth. t. 349, unpublished. (*R. Acetofella* ð; Linn. Sp. Pl. 482. *Acetosa* minor erecta, lobis multifidis; Bocc. Mus. v. 2. 164. t. 126. Tourn. Inst. 503.)—Flowers dioecious. Leaves lanceolate-hastate; their side lobes palmate.—Native of Italy, Sicily, and the Levant. Dr. Sibthorp gathered it on the hills of Greece, as well as near Constantinople. Linnæus seems never to have seen it, and has fallen into a strange error, in quoting Boccone's synonym for two different things, within four or five lines. This Willdenow did not presume to correct, but aggravated the error by one figure. He reminds us of the very submissive young man, who saw Rousseau eat the berries of *Hippophæe*, without daring to tell him they were reputed poisonous. The present species differs from the last merely in the divisions of its side lobes. We have never seen its *valves*, but the *flowers* are exactly like *Acetofella*, of which it may possibly be a variety.

38. *R. bidens*. Toothed-valved Sorrel. Brown n. 2.—“Flowers separated. Valves naked, hastate. Leaves linear-lanceolate, tapering at the base.”—Gathered by Mr. Brown, in Van Diemen's island. Whether this be dioecious or monoecious is not expressed.

39. *R. aculeatus*. Prickly-valved Sorrel. Linn. Sp. Pl. 482. Willd. n. 33. Sm. Prodr. Fl. Græc. Sibth. v. 1. 249. (*Acetosa cretica*, femine aculeato; Bauh. Prodr. 55. *Oxalis* minor aculeata Candix; Bauh. Hist. v. 2. 991.)—Flowers monoecious. Leaves lanceolate, stalked. Fruit reflexed. Valves fringed with hooked prickles.—Native of Spain, Crete, Greece, and the neighbourhood of Constantinople. A very curious little perennial species, somewhat like *Acetofella* in herbage, except that the *leaves* are more glaucous, and simply lanceolate, not hastate. The *clusters*, or *spikes*, are solitary at the top of each branch, and look at first sight like those of some *Reseda*. *Flowers* small, monoecious in both the Linnæan specimens, though on one there are more males, on the other more females. The latter are strongly curved downwards. *Valves* ovate, curiously fringed with rigid, hooked, or forked, prickles; some are furnished with a small *grain*.

40. *R. luxurians*. Spreading Cape Sorrel. Linn. Mant. 64. Suppl. 212. Willd. n. 34. (*R. fagittatus*; Thunb. Prodr. 67. *Acetosa montana pumila*, fegopiri folio; Bocc. Mus. v. 1. 165. t. 126?)—Flowers monoecious. Leaves hastate, taper-pointed; somewhat heart-shaped. Stem much branched, angular, diffuse. Valves orbicular, naked.—Native of the Cape of Good Hope, according to a speci-

men from Dr. Bladh, in the Linnæan herbarium. The synonym of Boecone, which surely can have nothing to do with this plant, caused it to be thought of Italian origin. Linnæus cultivated it at Upsal, and we have a specimen from the Paris garden, but our English cultivators seem to know nothing of this *Rumex*. The root is tuberous like *Spiræa Filipendula*, or *R. tuberosus*, n. 34, and, of course, perennial. Stems many, twelve or eighteen inches long, prostrate, branched, zigzag, leafy, marked with five angles, and striated. Leaves on long stalks, very acid, purplish at the margin, waved, but scarcely crenate; their form triangular, with taper spreading points; their length an inch and a half or two inches; and they are cut away at the base, up to the side ribs. Clusters terminal, numerous, composing a large spreading panicle, with fine, capillary, single-jointed partial stalks. Flowers certainly monoecious in the above-mentioned specimen, the only one we have seen; the males towards the extremity of the clusters. Calyx in both sexes oblong, incurved, concave, obtuse. Petals larger, orbicular, reddish. Stamens six, with oblong cloven anthers. Valves twice as large as the permanent inflexed calyx, orbicular, finely reticulated, and, as far as we can discover, destitute of grains. It might puzzle any reader to determine what the younger Linnæus meant, in the *Supplementum*, by the inner and outer valves. The latter are the calyx, but there is no authority, nor analogy, to justify his phraseology, nor is the calyx awl-shaped. We are enabled to solve Willdenow's difficulty concerning *R. spinosus* of Thunberg, as we have the real *spinosus* from the Cape, and the present plant answers so exactly to his *sagittatus*, a species apparently overlooked by Willdenow.

41. *R. arifolius*. Great Arum-leaved Sorrel. Linn. Suppl. 212. Willd. n. 35. Ait. n. 27. Allion. Pedem. v. 2. 204? (*R. abyssinicus*; Jacq. Hort. Vind. v. 3. 48. t. 98. *Acetosa montana lato ari rotundo folio*; Boec. Mus. v. 1. 165. t. 125? see also t. 126.)—Flowers dioecious. Leaves all stalked, hastate, with simple divaricated lobes. Valves heart-shaped, rounded, naked, entire.—This species is reported to have been brought from Abyssinia by Mr. Bruce, as every thing communicated by that celebrated traveller was, at one time, supposed to have been; just as the gardeners have since attributed every new plant, even the Great Barbary Oat, to Botany Bay. We can scarcely doubt that Allion's is the same species, for few plants vary more surprizingly in luxuriance than we have seen this; and if so, *R. arifolius* is a native of the Alps. We gathered it by the great high road over Mount Cenis, in 1787. To prevent mistakes, we shall describe our specimens, and leave our readers to observe how nearly they agree with Jacquin's luxuriant garden ones, which he says were from six to nine feet high. Root perennial. Stems from three to five feet high, erect, simple, leafy, somewhat angular, strongly furrowed, smooth, light green, often reddish. Leaves of a light bright green, not of the deep hue of *R. Acetosa*, from two to four inches long, sometimes more, oblong inclining to ovate, with two spreading, acute, entire lobes at the base, very variable in size. Footstalks very long in the lower and radical leaves, and scarcely entirely wanting in the uppermost. Clusters numerous, forming a large, terminal, compound, leafless panicle of innumerable, very small, green flowers, male on one plant, female on another. Calyx of the latter reflexed, permanent. Valves thrice as large, pale brown, tinged with pink, membranous, without grains, finely reticulated, nearly orbicular, wavy; but not crenate. Seed pale brown, above half the length of the valves, its angles sharp and greatly compressed. It must be observed that though Jacquin's figure, which is far from exquisitely

finished, seems to indicate grains on the valves, his description says there are none. We are not very doubtful of Boecone's synonym, as his figures are generally diminished, and our plant is so variable in size.

42. *R. bipinnatus*. Cut-leaved Sorrel. Linn. Suppl. 211. Willd. n. 36.—Flowers dioecious. Leaves doubly pinnatifid.—Native of Morocco, in sandy ground, according to a specimen in the Linnæan herbarium, the only one we have seen, which is just about flowering, and seems entirely male. Stem ascending, about a span long, simple, leafy, angular, striated, smooth. Leaves an inch or more in length, apparently very fleshy, heart-shaped, deeply pinnatifid almost to the mid-rib; their segments deeply, irregularly and obtusely subdivided, so that the whole leaf bears some resemblance to various species of PELARGONIUM; see that article. Footstalks about equal to the leaves, or longer. Stipulas large, membranous, pale, ovate, acute, sheathing at the base. Clusters composing a terminal panicle, with large shining bractæas, resembling the stipulas. Calyx of three roundish, concave, membranous-edged leaves. We can scarcely discern even the rudiments of petals. Stamens six, with oblong, reddish, cloven anthers.

43. *R. hoflilis*. Armed, or Prickly Dock. Loureir. Cochinch. 217.—Flowers dioecious. Leaves lanceolate, entire. Stem prickly. Valves naked.—Native of Cochinchina, where it is called *Cây dièd gai*. The stem is three feet high, erect, round, prickly. Leaves flat, spreading. Flowers spiked. Valves all without grains, entire, smooth, unarmed. Seed triangular. Petals three, greenish. Loureiro.

The author last named has a *R. crispus*, found near rivers in Cochinchina, which he mentions as eatable. This is very unlikely to be our Linnæan *crispus*, especially as he says each valve bears three bristles, nor was he at all acquainted with European plants, except from description. Still we dare not, without specimens, adopt the species in question as a new one.

RUMEX, in Gardening, contains plants of the herbaceous, perennial, and woody evergreen kinds, of which the species cultivated are, the common sorrel (*R. acetosa*); the French sorrel (*R. scutatus*); the patience dock, or rhubarb (*R. patientia*); the bloody-veined dock, or bloodwort (*R. sanguineus*); and the tree sorrel (*R. lunaria*).

In the first species the whole herb is acid, with a degree of astringency not unpleasent or unwholesome. It is often cultivated as a culinary herb. And there is a variety of it with broad leaves, termed great mountain sorrel.

The second sort, which is called round-leaved sorrel, is a more grateful acid than the first kind, and of course preferred for kitchen use, in soups, &c.

Method of Culture.—The first and second sorts and varieties of these plants may be increased by seed and parting the roots, but more particularly the first, as the latter may be very readily increased by the roots. The seeds should be sown in a bed or border in the early spring, as March, raking them in evenly. When the plants come up, they should be regularly thinned, and when of some growth, in the summer, be planted out in rows on a bed or border, about eight or nine inches apart in the common sort, and, in the other a foot or more, watering them well; when they will be proper to cut the latter end of the same summer and in the autumn, continuing for several years; but as the seedling plants in the first kind mostly produce larger leaves than the older plants, fresh supplies should be raised annually, or every other year. And the parted roots may be planted out in the same season, or in autumn, in rows a foot apart, giving them a good watering when they grow readily and

and furnish leaves in the latter end of summer and in the autumn. The second fort is readily raised in this way. They afterwards only require to be kept clean, and to have the feed-stems cut down in the summer, as well as the rank leaves in the autumn, that more full supplies of fresh leaves may be afforded.

And the third and fourth forts may be raised also from feeds in the same way, and the former from offsets of the root planted out in the autumnal season; when they grow very readily.

The last fort is easily increased by cuttings of the young shoots in the spring and summer months, being planted in pots at the former season, plunging them in a hot-bed; but in the latter they succeed without artificial heat, either in pots or the natural ground, being occasionally shaded and watered; when they become well rooted by the autumn. The third and fourth forts afford variety in the clumps and borders, and the last among the green-house collections of plants.

RUMEX, in the *Materia Medica*. The root of the R. aquaticus, or water-dock, has scarcely any smell; it has a strong austere taste, strikes a black colour in a solution of ferrum vitriolatum, or ferri sulphas, and yields its active matter both to water and to rectified spirit. All the lapathæ were formerly officinal herbs. Their name is derived from *λαπάθω*, *evacuus*, and they are alluded to by Horace in the following lines:

“ — Si dura moralitur alvus,  
Mitulus et viles pellent oblacula conchæ  
Et lapathi brevis herba.” Sat. 4. l. 2. v. 27.

The water-dock has been esteemed to be the most efficacious. The leaves, which manifest considerable acidity, are said to possess a laxative quality, and have therefore been used to relieve costiveness; the roots are strongly astringent, and have been much employed, both externally and internally, for the cure of scurvy, especially when the gums are spongy, and frequent hemorrhages supervene. It is also recommended in various other cutaneous discharges, and in visceral obstructions: and in order to give it additional importance, Muntingius has laboured to prove that this hydrolapathum is the “Herba Britannica” of the ancients; but many medical men still think that this root does not peculiarly differ from other astringents, and are so sceptical, as not to place any faith in the great virtues ascribed to it by Muntingius and sir John Hill; so that it is now scarcely ever employed. The powdered root is said by Murray to be an excellent dentifrice. The leaves of the R. acetosa, or common sorrel, have an agreeable acid taste, like that of oxalis acetosella, or wood-sorrel, which this plant resembles in its medical properties; and as it is easily procured in great abundance, may be substituted for it. (See OXALIS.) Sorrel, taken in considerable quantity, or used variously prepared as food, will undoubtedly be found beneficial, where a refrigerant and antiscorbutic regimen is required; and Linnæus informs us, that the Laplanders experience “ferum acetosatum” to be in this respect a useful and pleasant diet. The acidulous taste of sorrel-leaves is said to depend on the presence of superoxalate of potash, which they contain. The leaves are diuretic as well as refrigerant. Their expressed juice diluted with water, or a decoction of them in whey, affords an useful drink in cases of inflammatory fever; and eating them in large quantities daily as a salad, may prove serviceable in some cutaneous affections. In France the plant is cultivated for the use of the table. Woodville. Thomson.

RUMFORD, in *Geography*. See ROMFORD.

RUMFORD, a town of America, in Cumberland county, Maine, on the N. bank of Androscoggin river, about 80 miles N.W. of Portland. The township is about eight miles square, seven of which lie N. of Androscoggin river, which meanders through it about twelve miles; about a mile from its E. line there is a large fall. Ellis's river runs through it on the west side.

RUMFORD. See CONCORD.

RUMI, in the *Materia Medica*, a name given by Avicenna and Serapio to mastic of the finer kind. They distinguish this drug into two forts; the one called by this name *rumi*, which was white and pure; the other called *cupli*, which was foul and blackish; the former came from the island of Chios, the latter from some parts of Ægypt.

RUMI Ramba, in *Geography*, a plain near Quito, in Peru, full of large fragments of rocks, thrown thither from a volcano, formerly in the famous mountain of Pichincha.

RUMIGNY, a town of France, in the department of the Ardennes, and chief place of a canton, in the district of Rocroy; 12 miles S.W. of Rocroy. The place contains 779, and the canton 8944 inhabitants, on a territory of 230 kilometres, in 27 communes.

RUMILLY, a town of France, in the department of Mont-Blanc, and chief place of a canton, in the district of Annecy; 7 miles W.S.W. of Annecy. The place contains 2757, and the canton 13,585 inhabitants, on a territory of 197½ kilometres, in 26 communes.

RUMINANT, RUMINANS, in *Natural History*, an animal which chews over again what it has eat before: this is popularly called “chewing the cud.”

Joah. Con. Peyer has an express treatise “De Ruminantibus et Ruminacione,” where he shews, that there are some animals which do really ruminate, such as oxen, sheep, deers, goats, camels, hares, and squirrels; whereas others only appear to ruminate, which he calls *ruminantia spuria*; of which number are moles, crickets, bees, beetles, crabs, mullets, and several other fishes.

This latter class, he adds, have the stomachs composed of muscular fibres; by means of which the food is ground up and down, much as in real ruminants.

Ruminants, Mr. Ray observes, are all quadrupedal, hairy, and viviparous; some with hollow and perpetual horns, others with deciduous ones. See QUADRUPEDS.

The horned ruminants have all four stomachs appropriated to the office; viz. 1. The *κοιλία μεγάλη* of Aristotle, the *rumen*, *venter magnus*, or what we call the *paunch*, or *inward*, which receives the meat slightly chewed, retains it awhile, and then delivers it back again into the mouth, which is what we call the *cud*, to be re-chewed. 2. The *κεκευδαλος*, or *reticulum*, which we call the *honeycomb*, from its internal coat being divided into cells like honeycombs. 3. The *εσθνος*, which Mr. Ray thinks has been wrongly translated *omasus*, and which he chooses to call the *cebinus*: this being difficult to clear, our people throw it away, and call it the *manifold*. 4. The *ενυςτοι* of Aristotle, by Gaza called the *abomasus*; and, among us, the *maso*.

Again, all the horned ruminant animals want the dentes primores, or broad teeth in the upper jaw; and they afford that hard kind of fat called *suet*, *sebum*, *στάς*, which is firmer and less liquefiable in them than the adeps of other animals. See *Anatomy* of MAMMALIA.

It is remarked by Mr. Feron, that the retrograde motion of the œsophagus in ruminating cattle, such as cows, sheep, goats, &c. renders them capable of bringing up the softened grafs from their first stomach. But when these animals fill themselves too full of clover, or of wet grafs, or of some other young vegetables, which are liable to run into fermentation,

tation, the stomach becomes distended with air, and death frequently ensues. See CUD and HOVEN.

Great care is therefore to be taken with all these sorts of animals when they are first turned into rich full grassed pastures, to see that they do not stay in them too long at a time, or fill themselves too full of such rich food. They are best and safest when only put into them for a short period at any one time, on being first turned upon them. And the properest season for them, as well as the grass, is probably to consume it when it is in the dry state, as when eaten while very wet, there may be injurious consequences in both ways.

RUMINATION, in *Medicine*, which literally signifies *chewing the cud*, is applied by analogy to express one of the symptoms of indigestion, nearly allied to *rudation*, when the stomach, by repeated spasmodic efforts, throws up into the mouth, not only flatus and some of its secretions, but portions of the undigested food. Dr. Cullen defines *dyspepsia*, or indigestion, by enumerating this among other symptoms by which it is, in different instances, characterized. "Anorexia, nausea, vomitus, inflatio, ructus, *ruminatio*, &c." See his *Synops. Nosolog. Method. Gen.* 45. See RUCTATION, INDIGESTION, &c.

RUMINATION, in *Comparative Physiology*, a technical term equivalent to the common phrase of "chewing the cud." It denotes the ascent of the food from the paunch, or first stomach, into the mouth, and the second mastication which it there undergoes; a process confined to those mammalia which have complicated stomachs. When this second mastication has been accomplished, the food descends, not into the paunch, which receives it when it is first swallowed, but into the second stomach; and thence successively into the third and fourth. The mechanism, by which the animal has the power of conveying its food either into the paunch or the second stomach at will, as well as the structure of the stomach of ruminating animals altogether, is described in the article MAMMALIA. It is a singular example of voluntary power over the motions of an organ, which in other respects and in other animals are completely involuntary. "The influence of the will," says Blumenbach, "in the whole affair of rumination, is incontestible. It is not confined to any particular time, since the animal can delay it according to circumstances, when the paunch is quite full. It has been expressly stated of some men, who have had the power of ruminating (instances of which are not very rare), that it was quite voluntary with them. I have known two men who have ruminated their vegetable food: both assured me that they had a real enjoyment in doing this, which has also been observed of others: and one of them had the power of doing it or leaving it alone, according to circumstances." *Comparative Anatomy*, p. 138, note.

The final purpose of rumination, says the same author, as applicable to all the animals in which it takes place, and the chief utility of this wonderfully complicated function in the animal economy, are still completely unknown: what has been already suggested on these points is quite unsatisfactory. Fabricius ab Aquapendente has sufficiently refuted the old dream of Aristotle and Galen, that rumination supplied the place of incisor teeth, the materials of which are applied in these animals to the formation of horns. Perreault and others supposed that it contributed to their security; as they eat much, and are timid, they supposed it removed the necessity of their remaining long employed in chewing in an open pasture. But the Indian buffalo ruminates, although it does not fly even from a lion, but rather attacks, and often vanquishes that animal. And the wild goat dwells in alpine countries, which are inaccessible to beasts of prey. *Comparat. Anat. loc. cit.*

RUMMAGE, probably derived from the Saxon *raum*, *room*, or *space*, in the *Sea Language*, signifies to clear a ship's hold, or to remove goods or luggage from one place to another.

RUMMEL, in *Geography*, a river of Algiers, which passes by Constantina, and afterwards joins the Wed el Kibbeer, 18 miles N.W. of Constantina.

RUMMELSBURG, a town of Farther Pomerania, situated on the Wipper; 25 miles S. of Rugenwalde. N. lat. 53° 55'. E. long. 65° 53'.

RUMNEY. See ROMNEY.

RUMNEY, or *Romney Marsh*, a tract of land in the county of Kent, (see ROMNEY), governed by certain ancient and equitable laws of sewers, composed by Henry de Bathe, a venerable judge in the reign of king Henry III. who granted a charter to this district, empowering twenty-four men, thereunto chosen, to make distresses equally upon all those which have lands and tenements in the said marsh, to repair the walls and water-gates of the same, against the dangers of the sea. The commissioners of sewers, in other parts of England, may act according to the laws and customs of Rumney Marsh, or otherwise, at their own discretion; subject to the discretionary revision of the court of king's bench.

RUMNEY, or *Romney*, a township of New Hampshire, America, in Grafton county, on a north branch of Baker's river, about 7 or 8 miles N.W. of Plymouth, on the W. side of the Pemigewasset, incorporated in 1767, and containing 765 inhabitants.

RUMOUR, in *Law*. Spreading false rumours is criminal, and punishable at common law.

RUMP of a Bird. See UROPIGIUM, and *Anatomy of BIRDS*.

RUMPHIA, in *Botany*, was inscribed by Linnæus to the memory of George Everard Rumph, M.D. counsellor to the Dutch East India Company, whose remembrance must ever be dear to all students of tropical botany, for the sake of his *Herbarium Amboinense*. This work, of seven volumes folio, was the fruit of his long residence, and great authority, in Amboyna, nor does it, as a store of faithful practical information, fall short of any performance of the kind. It has indeed some of the faults, or rather misfortunes, of a posthumous publication; and the reader must always keep in mind that the figures, far inferior to those of the *Hortus Malabaricus*, are generally not more than half the size of nature. The original drawings, still in existence, are said to be very fine. The author was born at Hanau in 1637, and died in 1706. His ardour for natural science rose above the most formidable obstacles, such as the loss of sight, at forty-three years of age, and the destruction by fire of all his papers and collections, seven years afterwards. He published at Amsterdam, in 1706, a splendid and excellent work on shells in Dutch, and is said to have left behind him, in manuscript, a political history of Amboyna. Happy were it if his gentle and benevolent spirit tended, in any way, to meliorate the cruel and sordid policy of his countrymen there, or any where else! He was a member of the Imperial Academy *Naturæ Curiosorum*, and well designated by that body, according to their customary mode, as the Indian Pliny.—Linn. Gen. Pl. 23. Schreb. 31. Willd. Sp. Pl. v. 1. 187. Mart. Mill. Dict. v. 4. Vahl. Enum. v. 2. 36. Juss. 370. Lamarck Illustr. t. 25.—Class and order, *Triandria Monogynia*. Nat. Ord. *Tricocceæ*, Linn. *Terebintaceæ*? Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, three-cleft, erect, flat. *Cor.* Petals three, oblong, obtuse, equal, much exceeding the calyx. *Stam.* Filaments three, awl-shaped, the

the length of the corolla; anthers small. *Pist.* Germen superior, roundish; style awl-shaped, the length of the stamens; stigma triangular. *Peric.* Drupa coriaceous, turbinate, with three furrows. *Seed.* Nut ovate, undivided, of three cells.

*Eff. Ch.* Calyx three-cleft. Petals three. Drupa coriaceous. Nut of three cells.

1. *R. amboinensis.* Linn. Sp. Pl. 49. (Tsjem-tani; Rheede Hort. Malab. v. 4. 25. t. 11. Myxa pyriformis, officulo trispermo; Raii Hist. v. 2. 1556.)—Native of wild stony sandy places, in the hills of Parakaroo, and other parts of the country of Malabar, flowering in December, and bearing fruit in January, which remains long on the branches. This is a tree of vast size, with a thick trunk, and rough bark. Leaves evergreen, scattered, stalked, heart-shaped, pointed, sharply crenate, with five radiating branched ribs, roughish and hairy; dark green on the upper side; paler beneath. Flowers white, in axillary clusters. They are represented with a hairy tubular calyx, and three seeming bracteas at the base; but the latter appear to be what Linnæus describes as the calyx. We have seen no specimen, nor do we know whence he formed his generic description, which certainly does not accord, in the last-mentioned respect, with Rheede's plate. The aromatic, accecent, or somewhat acrid, qualities attributed to the plant by this writer, justify Jussieu's opinion of its natural affinities. The specific name, *amboinensis*, is either incorrect, or must have been founded on the authority of a specimen from Amboyna, seen perhaps by Linnæus, but of which no record remains.

RUMPNEY, in *Geography.* See REMNEY.

RUMSEY. See ROMSEY.

RUMZE, a river of Moravia, which runs into the March, 15 miles S. of Olmutz.

RUN of a Ship, so much of her hull as is always under water; growing thinner and lankier by degrees, from the floor-timber to the stern-polls.

This is also called the *ship's way aftward.*

A ship is said to have a good run, when it is long, and the water passes easily to her rudder, her tuck not lying too low, which is of great importance to her sailing. If the water do not come strongly to her rudder, by reason of her being built too broad below, she cannot steer well; and a ship that cannot steer well, cannot keep a good wind, nor will have any fresh way through the sea, but will always be falling to leeward.

And yet a ship with a large and good run loses much stowage, because it is made narrow below.

RUN, in the *Manege.* To run a horse is to put him to his utmost speed. Some use the word *running* for any kind of gallop.

RUN Out, in *Agriculture*, a provincial term applied to land that is exhaulted. It also signifies to *sprout* as corn in a wet harvest; and likewise to *scour*, as in the cases of cattle.

It is a very bad and mischievous practice, though one which is too much indulged in by farmers in many places, to suffer lands to be quite run out, as they are very difficult, troublesome, and expensive to bring into order again; and in a great many cases, it is almost impossible ever to restore them to the same state of cultivation they were in before such injuries happened to them. As such ill consequences are, therefore, not unfrequently caused in an intentional manner, it may be necessary to provide against them by the insertion of suitable clauses in leases.

RUNS, a term used for the lines of planks on which the navigators wheel their barrows, when employed in the

excavation of a canal. In some instances the same term has been applied to inclined planes.

RUNACHUSAN, in *Geography*, a small island near the W. coast of Scotland. N. lat. 58° 13'. W. long. 5° 4'.

RUNAN, a town of Prussia, in Ermeland; 4 miles N.W. of Heilsberg.

RUNAWAY BAY, a bay on the N.W. coast of the island of Antigua, between the fort on Corbizon's point N., and fort Hamilton S.—Also, a bay on the N. coast of Jamaica, W. of Great Laughlands river and Mumby bay, and 9 or 10 miles E. of Rio Bueno. N. lat. 18° 30'. W. long. 77° 11'.

RUNAWAY, *Cape*, a cape on the E. coast of New Zealand; so called by Cook in 1769, from the hasty retreat of the enemy, after having threatened hostilities. S. lat. 37° 32'. W. long. 181° 48'.

RUNCARIA, in our *Old Writers*, signifies land full of brambles and briars. (1 Infl. 5.) The word comes from the Latin *runca*, a weed.

RUNCATION, a term used in the *Ancient Husbandry* to express the clearing away the weeds from among the corn, and other sown plants.

They used, when the corn or other plants were an inch or two high, to draw a sort of rake or harrow over the ground indiscriminately over the corn and weeds, and when this was done, a person followed over all the field, and picked up all the weeds with the hand: the treading down the young corn, however, by this person's feet, and the injury done to it by the rake, were so great, that the crop always suffered greatly by it; and many of the Romans chose to omit the use of the rake or harrow, as a thing that did as much injury to the corn as to the weeds, and contented themselves with the sending a person to pick up the weeds without it.

This was a sort of first hint to the horschoeing husbandry of the moderns, though so injudiciously managed, that it was of very little, if any use, in this its infancy. But had these farmers been instructed to sow their corn in rows, and then to use the rake or harrow, as we do the hoe, only between those rows, they would then have had all the advantage of destroying weeds by it, and of stirring the earth, and no injury would have been done to the crop. See HUSBANDRY.

RUNCHEs, in *Agriculture*, a term applied to charlock when dry and withered.

RUNCINATUM, FOLIUM, in *Botany* See LEAF.

RUNCOL, in *Geography*, a town of Walachia; 15 miles N.W. of Tergofyl.

RUNCORN, a large township, royalty, and parish, in the western division of the hundred of Bucklow, county palatine of Chester, England, is situated on the S. bank of the river Mersey, at the distance of about 14 miles N.E. from the city of Chester. The royalty belongs to the earl of Cholmondeley, as annexed to the honour of Halton. Runcorn appears to have been anciently a town of considerable consequence. Ethelfleda, the celebrated sister of king Edward the Elder, built a castle here, some traces of which can still be discovered on an eminence called the Castle Rock, situated about a quarter of a mile from the parish church. This fortress must have been important, as it commanded the passage from the kingdom of Mercia to that of Northumberland. In the year 1133, a priory for regular canons of the Augustine order was founded at Runcorn by William Fitz-Nigel, but they were shortly afterwards removed to Norton. The church, which belonged to this monastery, contains monuments in memory

of sir John Cheslyre, prime serjeant to queen Anne and king George I. who died in 1738, and also of three baronets of the Brooke family. Those of sir Richard Brooke, who deceased in 1781, and the late sir Richard, who died in 1795, were executed in marble by John Bacon, sculptor. Since the formation of the duke of Bridgewater's canal, which joins the Mersey close to Runcorn, this place has greatly increased in population and wealth, and has been improved by the erection of many handsome buildings. For some years past it has likewise been a fashionable resort for change of air and salt-water bathing.

The parish of Runcorn is extensive, and comprises nineteen townships. According to the population returns of 1811, the parish contained 1171 houses, and 6317 inhabitants, of whom 2060 resided in the township of Runcorn. Here are many fine quarries of free-stone, large quantities of which are sent by water-carriage to Chester, Liverpool, Manchester, and various other places. Lysons's *Magna Britannia*, vol. ii. Cheshire, 4to. Lond. 1810. *Beauties of England*, &c. vol. ii.

RUNDAL, a river of Norway, which runs into the sea, near Bergen.

RUNDENDORF, a town of Bavaria, in the bishopric of Bamberg; 7 miles N.N.W. of Bamberg.

RUNDLES, or ROUNDLES, in *Heraldry*, the same as balls or pellets.

RUNDLET, RONLET, or *Roundlet*, a small vessel, containing an uncertain quantity of any liquor, from three to twenty gallons.

RUNDULLA, in *Geography*, a town of Hindoostan, in Baglana; 10 miles E. of Naderbar.

RUNEHOLM. See RUUN.

RUNEKA, in *Hindoo Mythology*, is fabled as the mortal mother of Parafu Rama, an incarnation of Vishnu. Her husband was Jamadagni, one of the seven Rishis, or patriarchal sages. Under these several names or words explanations will be respectively found. On the death of Jamadagni, as related in that article, Runeka declared her intention of becoming Sati, that is *pure*, by the act of self-immolation on her husband's funeral pile. (See SATI.) The avaricious Raja, who had caused her husband's death, became thus charged with this double murder, and the vindictive Sati imprecated curses on him and his tribe, enjoining their valorous son Rama to avenge the death of his parents by the condign punishment of the impious Raja and the military tribe of Kshetria, (see *SECTS of Hindoos*,) whose measure of iniquity and oppression was completed by this final atrocity.

The prayers or imprecations of a Sati are never inefficiently uttered; the great gods themselves cannot listen to them unmoved. Vishnu accordingly inspired Rama with a portion of his divinity, and sent him forth to combat the Raja; who, after twenty battles, was slain, the military race of Kshetria annihilated, and his usurped kingdoms relieved from oppression.

On the occasion of this self-immolation of Runeka, it is related, that to strengthen the potency of her maledictions on the head of the murderous Raja, she, in addition to her own self-sacrifice, performed also the ceremony of Narmedha, or the sacrifice of a man, thereby rendering her solicitations to the avenging deities absolutely irresistible. And so lasting is said to be the effect of the wrath felt and transmitted by the vindictive Sati, and its attendant sacrifice and incantations, (see *MANTRA* and *NARMEDHA*,) that nothing can avert its severity, continued even to the present day, but a counteracting Narmedha; and that with the permission of Parafu Rama (who is considered as still living in the Kokan or Concan): a man is accordingly sacrificed to appease the

wrath of Runeka Devi, in every generation, by the tribe called Karhara, a military sect, many of whom are settled in the Kokan, Guzerat, and other western provinces of India.

Mr. Wilford, discussing some of these topics in the third volume of the *Asiatic Researches*, observes, that although human victims, Narmedha, allowed by ancient authorities, are now prohibited under pain of the severest torments in the next world, the prohibition is said to be disregarded by the Pamaras, or Pariar races, in different parts of India. But he cannot imagine that any Brahman would now officiate at so horrid a ceremony, denounced as it is in the *Brahma* and *Aditya Puranas*, and in the *Sri Bhagavat* itself.

Notwithstanding, however, the general incredibility of the fact, researches have since brought to light that a tribe of Brahmans, called, from officiating for that tribe, Karhara Brahmans, do still actually countenance and practise the horrible ceremony in question. They bear, at all events, the odium of it, and are consequently shunned by their holy brethren of more humane practices and tribes. They are themselves very reserved on the subject; and deny the present practice, but admit of its former existence. On this curious point many particulars, for which we have not room, are collected in Moor's *Treatise on Hindoo Infanticide*; to which, p. 195, we refer those desirous of farther information. Instances of recent sacrifices, and the names of the supposed victims, are there given.

The name of this maleficent lady is sometimes written Renuci, and Renuka. In the eleventh volume of the *Asiatic Researches* the following passage occurs, descriptive of her person and family. "In the white Island," which in passing we will observe Mr. Wilford endeavours to prove to be Albion, "lived Jamadagni, a great Muni (see MUNI), who can at his will destroy the world, who bestows rewards and inflicts punishments, knows the past and the future, and of whom the gods stand in awe. His wife was Renuka; in her manners and gait she is like Reti, the mother of Kama. (See those articles.) The whole world gazed at her with astonishment: her eyes are more beautiful than those of the antelope of the forest; her face is like the moon; she is a goddess, incapable of decay, immediately born of the supreme being. She is Iswari, the sovereign queen (see ISWARA); from her was born Rama, ever victorious," &c.

RUNGA, in *Geography*, a town of Hindoostan, in the circar of Cicacole; 25 miles S.W. of Cicacole.

RUNGIS, a town of France; 6 miles S. of Paris.

RUNGPOUR, a circar of Hindoostan, bounded on the N. by Coos Beyhar, on the E. by the Burhampooter, on the S. by Goragot, and on the W. by Dinagepour and Surroopour. The capital is Rungpour.

RUNGPOUR, a town of Bengal; 72 miles N.E. of Mauldah. N. lat. 24° 43'. E. long. 89° 23'.

RUNGS, in a *Ship*, the same with the floor or ground-timbers, being the timbers which constitute her floor, and are bolted to the keel, whose ends are called *rung-heads*; and more properly floor-heads.

*Rung-Heads* are made a little bending to direct the sweep or mold of the futtocks, and naval timbers; for here the lines, which make the compass and bearing of a ship, do begin.

RUNIC, a term applied to the language and letters of the ancient Goths, Danes, and other northern nations.

The word *rune*, according to Mallet, is derived from a word in the ancient Gothic language, signifying *to cut*: but Wormius, with greater probability, derives *rune* from either *ryn*, a *furrow*, or *ren*, a *gutter* or *channel*. As these characters were first cut in wood or stone, the resemblance

to a furrow, or channel, would easily suggest the appellation. Others, however, derive the term from *ryne*, signifying art, especially that of magic.

Some have been of opinion that Gulphilas, or Ulphilas, a Gothic bishop, about the year 370, was the first inventor of the Runic character: but Olaus Wormius shews at large, that Ulphilas could only be the first who taught it to foreigners; for that the Runæ, or characters themselves, were older than he.

In reality, Ulphilas, according to other authors, was so far even from teaching the character, that he invented an alphabet of his own, on purpose to put the Runic characters, which had been made subservient to the superstitions of heathenism, out of use. See *GOTHIC Character*.

Many learned writers have adopted the opinion, first suggested by Dr. Hickes, that the Runic character was borrowed from the Roman, and they farther maintain, that it was not known in the North before the introduction of Christianity. If it were allowed, that the Runic characters are borrowed from the Roman alphabet, it by no means follows, that the Scandinavians had waited for the secret till the introduction of Christianity among them: but it is justly observed by Wormius, that they are as easily reducible to the Greek and Hebrew alphabets as to the Roman. An evident proof that the Runic were not derived from the Roman letters, results not only from their form, which has scarcely any resemblance to these, but from their number (being but 16), and their order and names, which have nothing in common with the Roman, Greek, or Gothic characters of Ulphilas. A comparative view of the Runic and Gothic in these respects may be seen in the English translation of Mallet's Northern Antiquities, vol. i. p. 370. M. Mallet has sufficiently shewn, that all the old chronicles and poems of the North universally agree in assigning to the Runic characters a very remote antiquity, and in attributing the invention of them to Odin or Woden himself, whom their poets expressly call the inventor of the Runes. Besides, instances occur of princes and pagan heroes, who made use of this character in an age long before Christianity had penetrated into the North.

In Blekingia, a province of Sweden, there is a road cut through a rock, on which are various Runic characters, said to have been engraved there by king Harold Hylde-tand, in honour of his father; and king Harold is said to have ascended the throne about the beginning of the seventh century. It is, therefore, extremely probable that Odin introduced the Runic characters into the North, intending by the introduction of letters and writing to acquire respect from the rude uncivilized inhabitants of Scandinavia; who would be ready enough to conceive that there was something divine or magical in them. Accordingly we find, that they were actually employed, in spells and enchantments, for the pretended purpose of working prodigies.

A few years before the birth of Christ, as it has been said, soon after Mithridates had been overthrown by Pompey, a nation of Asiatic Goths, who possessed that region of Asia which is now called Georgia, and is connected on the south with Persia, alarmed at the progressive encroachments of the Roman armies, retired in vast multitudes under the conduct of their leader Odin, or Woden, into the northern parts of Europe, not subject to the Roman government, and settled in Denmark, Norway, Sweden, and other districts of the Scandinavian territory. As they brought with them many useful arts, particularly the knowledge of letters, which Odin is said to have invented, they were hospitably received by the natives, and by degrees acquired a safe and peaceable establishment in the new country, which seems to have adopted their language, laws, and re-

ligion. Odin is said to have been styled a god by the Scandinavians; an appellation which the superior address and specious abilities of this Asiatic chief easily extorted from a more savage and uncivilized people.

This migration is confirmed by the concurrent testimonies of various historians: but there is no better evidence of it, than that conspicuous similarity subsisting at this day between several customs of the Georgians, as described by Chardin, and those of certain cantons of Norway and Sweden, which have preserved their ancient manners in the purest degree. Not that other striking implicit and internal proofs, which often carry more conviction than direct historical assertions, are wanting to point out this migration. The ancient inhabitants of Denmark and Norway inscribed the exploits of their kings and heroes on rocks, in characters called Runic; and of this practice many marks are said still to remain in those countries. This art or custom of writing on rocks is Asiatic. Modern travellers report, that there are Runic inscriptions now existing in the deserts of Tartary. (See Voyage par Strahleberg, &c. A Description of the northern and eastern parts of Europe and Asia.) Schroder says, from Olaus Rudbeckius, that Runes, or letters, were invented by Magog the Scythian, and communicated to Tuifco, the celebrated German chieftain, in the year of the world 1799. (Præf. ad Lexicon Latino-Scandic.) The *written mountains* of the Jews are an instance that this fashion was oriental. On the subject of this migration, allowed by some writers and contested by others, see the articles *GOTHUS* and *ODIN*.

The Runic characters were distinguished into various kinds. The *noxious*, or *bitter Runes* were employed to bring various evils on their enemies; the *favourable* averted misfortunes; the *victorious* produced conquest to those who used them; the *medicinal* were inscribed on the leaves of trees for healing; others served to dispel melancholy thoughts, to prevent shipwreck, as antidotes against poison, as preservatives against the resentment of their enemies, and in order to render a mistress favourable. These various kinds differed only in the ceremonies observed in writing them, in the materials on which they were written, in the place where they were exposed, in the manner in which the lines were drawn, whether in the form of a circle, a serpent, or a triangle, &c.

The Runic characters were also employed for more rational purposes: for writing epistles and epitaphs, and for various kinds of inscriptions, which, the older they are, so much the better are they engraven. They are rarely written from the right hand to the left; but it is not uncommon to meet with the line running from the top to the bottom, after the manner of the Chinese and other Indian nations; or from the top to the bottom, and then turning round to the left, and so up again to the place it begins at; or else from the left to the right, and so back to the left again, which was the manner of the early Greeks. The greater part of the ancient monuments written in the Runic character, which are still preserved, consists of inscriptions dispersed here and there in the fields, and cut out on large stones or pieces of rock. They are also found in churches, and sometimes in other buildings.

The Saxons, who were fond of tracing the descent of their princes from Odin, and who became possessors of England in the sixth century, imported into this country the old Runic language and letters. This appears from inscriptions on coins, stones, and other monuments, and from some of their MSS.

There are some Runic medals in the closets of the curious; and some modern Danish and English medals, the inscriptions of which are Latin, and the character Runic.

There

There is extant a coin of king Offa with a Runic inscription, which shews, that this character had been used by the Saxons as well as their Scandinavian brethren.

There are also Runic inscriptions in this island; one in Cumberland, and another in Scotland. See Hicckes' *Thef. Ling. Sept.*

But the conversion of the Saxons to Christianity, which happened before the seventh century, entirely banished the common use of those characters, which were esteemed unhallowed and necromantic; and with their ancient superstitions, which yet prevailed for some time in the popular belief, abolished in some measure their native and original vein of poetical fabling. They suddenly became a mild and polished people, addicted to the arts of peace and the exercise of devotion; and the poems they have left us are chiefly moral rhapsodies, scriptural histories, and religious invocations, intermixed even with frequent allusions to the old Scaldic fables and heroes. See *SCALDS.*

We may here observe, that the enchantments of the Runic poetry are very different from those in our romances of Enchiridion. The former chiefly deal in spells and charms, such as would preserve from poison, blunt the weapons of an enemy, procure victory, allay a tempest, cure bodily diseases, or call the dead from their tombs; in uttering a form of words, or inscribing Runic characters; whereas the magicians of romance are chiefly employed in forming and conducting a train of deceptions. In the incantations of the former there is an air of barbaric horror; the latter often present visions of pleasure and delight; and although not without their alarming terrors, sometimes lead us through flowery forests, and raise up palaces glittering with gold and precious stones. The Runic magic is more like that of Canidia, in Horace; the romantic resembles that of Armida, in Tasso. The operations of the one are frequently but mere tricks, in comparison of that sublime solemnity of necromantic machinery, which the other so awfully displays.

In the tenth and eleventh centuries the Runic gave way to the Roman character; till at length the missionaries succeeded in totally abolishing them, as tending to retain the people in their ancient superstitions. It is said that the Goths, when they became Christians, manifested a blind and indiscreet zeal in destroying several ancient monuments, and burning a great number of books, because they were written with those characters; and that about the year 1001, the Runic characters were quite laid aside in Sweden, and the Roman letters taken in their room, the Swedes being persuaded to adopt this measure by the pope, and by Sigfrid, a British bishop. In Spain they were forbidden in 1136 by Alphonso, king of Castille and Navarre, and condemned by the council of Toledo in 1115. They are, however, still retained among the mountaineers of one province in Sweden. Mallet's *Northern Ant.* vol. i. p. 359, &c.

It is supposed they were called Runic, as being mysterious and scientific, like the Egyptian hieroglyphics. See Wormius de *Literatura Runica*; and Hicckes's *Theaurus of the ancient Northern Languages.*

In several parts of Sweden, stones may be met with, which were formerly set up as obelisks in memory of the dead; and these monuments are marked with the ancient northern letters called *Runor*, or the Runic characters. In some places the characters vary from the Runic, particularly in free-stones found in Helsingland, of which Mr. Celsius has given us a description, with an explanation. See *Philos. Trans.* N<sup>o</sup> 445. sect. 3.

From these Helsingland inscriptions an alphabet of sixteen letters may be derived, which is very singular. In

other alphabets different sounds are generally denoted by different figures; but here the same character, according to the diversity of its place and altitude between two parallels, denotes different sounds.

But these characters, however different they may appear at the first sight from the Runic, may easily be derived from them; or, *vice versâ*, the Runic may be derived from the Helsingic, if these be supposed the most ancient. The subtraction of a perpendicular line in the first case, or its addition in the latter, brings the two characters to a near resemblance.

The inscription, which Mr. Celsius considers, was published in *Monf. de la Motraye's Travels*, but erroneously.

*Runic Staffs* were a kind of calendars or compendious almanacs used in the North, marked out by lines upon short pieces of board or smooth sticks; some of which bear the appearance of great antiquity. They were called, in the North, *rim-stocks* and *prim-staffs*; and exhibited, by different lines or marks, the fasts and festivals, the golden number, Dominical letter, epact, &c. Dr. Plot, in his *History of Staffordshire*, p. 418, &c. describes one of these instruments under the name of a *clog*, and illustrates the construction of it by a figure. He observes, that this kind of almanac is a remain of the Danish government, and that it was still in use amongst the meaner sort of people. Those which he met with in Staffordshire had only the prime and immoveable feasts upon them; whereas others of a more perfect kind, preserved in the cabinets of the curious, have likewise the Dominical letters. And of those imperfect ones there are two kinds; some public, of a larger size, which were commonly hung at one end of the mantletree of the chimney, for the use of the whole family, as Wormius informs us they disposed of them in Denmark; and others private, of a smaller size, which they carried in their pockets. This chronological instrument is sometimes, by an evident corruption, called *runstock*.

*RUNJETZ*, in *Geography*, a town of Bohemia, in the circle of Chrudim; nine miles N. of Chrudim.

*RUNIUS, JOHN*, in *Biography*, one of the most celebrated of the Swedish poets, was born at West Gothland in 1679. Having received the early parts of his education at Skara, he went, in 1700, to Upsal, and after completing his studies, was appointed by count Stromberg to be his secretary. He died at Stockholm of a consumption in 1713, in the 35th year of his age. He is said to have written Swedish poetry at the age of 18, which displayed great beauty, and afterwards produced a variety of pieces on different subjects, which added very greatly to his poetical fame. He wrote with so much care, and his versification is so smooth and pleasing to the ear, that he is accounted by the Swedes one of the most successful of their poets. "Some of his poems are said to be very excellent, but many of them bear evident marks of carelessness and haste, for he experienced the common lot of genius, having been doomed, throughout life, to struggle with all the ills of poverty; and his distresses would have pressed upon him much heavier, had he not been frequently relieved by count Stromberg." His poems, which he began to collect in his life-time, when he found that they were in general request, were published, after his decease, under the title of "*Dudaim*," Stockholm, 1714, in two parts; the first contains sacred poems, and the second epithalamia, epitaphs, and congratulatory odes. In 1733 both parts were reprinted, with the addition of a third, containing pieces on different subjects, among which were several poems written in Greek, French, and German. *Gen. Biog.*

*RUNKEL*, in *Geography*, a town of Germany, in the county of Wied-Runkel, situated on the Lahn, and consisting

siting of about 120 houses. It has a citadel belonging to it, seated on a high hill, which was formerly the residence of the counts. The subsistence of the inhabitants is derived from agriculture, gardening, and the breeding of cattle. In the year 1634, this town was plundered and reduced to ashes by the Croats; 14 miles E. of Nassau. N. lat. 50° 23'. E. long. 8° 7'.

RUNN, a lake of Sweden, in the province of Dalecarlia; four miles S. of Fahlun.

RUNNAGAUT, a town of Bengal; 15 miles S. of Kishenagur.

RUNNEAH, a town of Hindoostan, in Candeish; four miles N.E. of Peploud.

RUNNEL, in *Rural Economy*, a term signifying a sort of rill.

RUNNEL is also used to signify pollard wood.

RUNNER, in the *Sea Language*, a rope belonging to the garnet, and to the two bolt-tackles. It is reeved in a single block, seized to the end of a pennant, and has at one end a noose to hitch into any thing, and at the other end a double block, into which is reeved the fall of the tackle, or the garnet; by which means it purchases more than the tackle or garnet could allow.

To *overhale the runner* is to pull down the hooked end, and hitch it into the sling.

RUNNET. See RENNET.

Aristotle will have the rennet to be the proper substance of the milk; but he is mistaken when he says it is found in all animals which give milk, especially in all ruminants.

RUNNING, in *Antiquity*, made one of the exercises performed in the *pentathlon*, (which see,) or *quinqertium*. See RACE and STADIUM.

This exercise was in so great esteem among the ancient Greeks, that such as prepared themselves for it, thought it worth their while to burn, or parch their spleen, because it was believed to be a hindrance to them.

Indeed, all those exercises that conduced to fit men for war, were more especially valued; and that swiftness was esteemed such in an eminent degree, appears from Homer's giving his hero the epithet of ποδας οκυς; Αχιλλευς.

RUNNING of the Eyes, in infants. See INFANT.

RUNNING-Fights, at sea. See FIGHTS.

RUNNING-Fire. See FIRE.

RUNNING out a Warp, in *Sea Language*, the act of carrying the end of a rope out from the ship in a boat, and fastening it to some distant place, to remove the ship towards the said place, or keep her steady while her anchors are lifted, &c.

RUNNING Rigging denotes all that part of a ship's rigging which passes through the blocks, to dilate, contract, or traverse the sails. See RIGGING.

RUNNING the Gauntlet, in *Military Language*. See GANT-LOPE.

RUNNING of Goods, a clandestine landing of goods, without paying the legal customs or duties for the same. See SMUGGLING.

RUNNING-Saddle. See SADDLE.

RUNNING-Blowb, or Frusb, in *Furriery*, denotes an imposthume, that sometimes gathers in a horse's frog; or a scabby and ulcerous disposition which sometimes causes it to fall off. When this discharge is natural, the feet should be kept merely clean. When an imposthume appears, the safest course is to pare out the hard part of the frog, or that which appears rotten, and to wash the bottom of the foot three times a day with old chamber-ley. But if a horse has been neglected, and there be a strong flux to the part, it will be necessary, in order to prevent its degenerating into a canker,

to bathe the thrush with the following lotion, laying over the ulcer a little tow dipped in the same, and using the purges and diuretics recommended in the greafe. Take spirit of wine and vinegar, of each two ounces; tincture of myrrh and aloes, one ounce; Ægyptiacum, half an ounce; and mix them together. See Bartlet.

RUNNING, in *Rural Economy*, a provincial term signifying rennet, or the coagulum made use of in cheese-making.

RUNNING Bull, in *Agriculture*, a term applied to the part of a harrow where the draught is attached in some cases. See HARROW.

RUNNO, in *Geography*, an island near the E. coast of Sweden, in the Baltic. N. lat. 57° 51'. E. long. 16° 33'.

RUNNODE, a town of Hindoostan, in the Malwa country; 30 miles N.W. of Chanderec. N. lat. 25° 7'. E. long. 78° 15'.

RUNNYMEAD, or RUNNEMEAD, a tract of land on the south bank of the river Thames, in the parish of Egham, and county of Surrey, England, is celebrated in history for the ever memorable conference which occurred here between king John and his barons, in the year 1215. In that conference the articles of Magna Charta, or the Great Charter, as it is called, by way of eminence, were agreed upon; and on the 15th of June the same was formally signed and sealed by the monarch, and a copy of it ordered to be deposited in the record office of each county. A small island in the Thames, adjoining the Mead, still retains the appellation of Magna Charta island, from a tradition that the charter was actually signed on that spot. There is at present a house upon it, and a ferry for foot passengers to Ankerwyke. It is said that Runnemead was used, in Saxon times, for holding councils. If so, observes Mr. Bray in "The History and Antiquities of the County of Surrey," its name may have been derived from the Saxon word "Rune, signifying council, the council mead." It contains about 160 acres of ground, title free, and is the property of ten persons, who have the sole use of it from March to the 12th of August, when it becomes common to all the parishioners of Egham, who turn out upon it an indefinite number of cattle; but in the last week of the same month it is appropriated as a race course, in conjunction with some adjoining inclosed lands, which are thrown open for the occasion. Near Runnymede are two meadows, called Long-mead and Yard-mead, to the southward of which the land rises to a ridge of hills, one of which, called Cooper's hill, has been immortalized by the strains of the poet Denham. The Roman road from London to Silchester passed through Runnymede. The History and Antiquities of the County of Surrey, by the Rev. Owen Manning, continued by W. Bray, esq. F.S.A., of Shire, vol. iii. Lond. 1814, fol.

RUNO. See RUNX.

RUNOR. See RUNC.

RUNRIG, in *Agriculture*, an ancient inconvenient distribution of common field land, by which small portions of land were let to different individuals in a mixed manner.

The circumstances of land being distributed in alternate ridges as the property or possession of different tenants or holders, was unquestionably a consequence of early farming townships. It is a sort of arrangement which must have first taken place on account of some imperfect and confused notion or intention of doing justice in an equal manner to all the tenants or holders of land in such farming villages, by allotting to, or bestowing upon, every one of them the same number of ridges near their houses, and an equal number in remote situations. And in order to render the absurdity of such a mode of holding and occupying land still more preposterously complete, if possible, such ridges were,

in many cases, not unfrequently exchanged; so that one tenant possessed, in the succeeding year, the land which was held or occupied by his neighbour the preceding one.

It is remarked, that in many parts of the highlands of Scotland, the land under this distribution has been first ploughed, without leaving any boundaries, except the furrows between the ridges; then the field was divided, by putting small branches of trees into the ground, in order to mark off every tenant's portion before the field was sown. No man knew his own land until the seed was to be put into the ground; and it became almost impossible for him to have the same portion of land any two successive years. This is a mode of division, it is supposed, which is analogous to that which Cæsar has asserted to have prevailed among the ancient Gauls; which must absolutely debar the very least improvement.

This inconvenient and improper method of proceeding was greatly fostered by the feudal notions of the times; in which he that could muster the greatest number of retainers, generally constituted to himself the greatest estate. But in the present times nothing can be more absurd than to see two or three, or perhaps four men, yoking their horses together in one plough, and having their ridges alternately in the same field, with or without a bank of unploughed land between them, by way of boundary. These diminutive possessions, it is said, were carried to such a length, that in some parts of Scotland, towards the northern extremity, the term a *horse's foot*, the sixteenth part of a plough-gate of land, is not yet wholly laid aside. The land is stated to be like a piece of striped cloth, with banks full of weeds and ridges of corn in constant succession, from one end of a field to the other. Under such management, all such occupiers or possessors must have concurred in one opinion with regard to the time and manner of ploughing every field, the kind of grain to be sown, the season and weather fit for sowing, and whether they and their horses were to be employed or idle. So late as even thirty or forty years ago, this practice is stated to have prevailed, not only over the greater part of the county of Perth, but, with very few exceptions, over all other parts of Scotland. Since that period, however, it has been, it is said, gradually going into disuse; and that the benefit of laying it aside entirely is so apparent, that any remains of the runrig system, which may still be met with, must soon give way and disappear, except, it is supposed, where the landlord is as much a Goth as his tenants.

When the various avocations, which these tenants must have, and the frequent jarring animosities which must necessarily arise in a close neighbourhood, where opposite interests are constantly interfering, are fully considered, it is supposed impossible to expect, that under such a system any species of improvement can be undertaken or carried on. In short, townships and runrig are supposed such obstacles to improvement, and bolt the door so firmly against all good cultivation, that it cannot have the least entrance; they are consequently greatly destructive of all good management; and besides, hold the people in the chains of idleness and poverty wherever they may be found to prevail. It is only by the proper separation, division, and inclosure of land into distinct portions, whether small or large, for each individual tenant, occupier, or proprietor, that it can be cultivated and improved in the best manner, and to the greatest advantage.

RUNSH, in *Husbandry*, a term provincially applied to the troublesome weed wild mustard or charlock.

RUNSTYCKEN, or ORE, in *Commerce*, a money of account in Sweden, being the twelfth part of the skilling, and 48 skillings being = a riksdaler. Also a copper coin, of 1 ore koppar and half runstycken: the other copper

coins are single and double slants, at 1 and 2 ore silver, or 3 and 6 ore koppar: 96 double slants, 192 single slants, or 576 runstycken, are to pass for 1 specie riksdaler; but in large payments, no person is obliged to take more copper coin than the value of half a riksdaler. *UN. Camb.*

RUNT, the name used, with the distinction of places, for several species of pigeons. These are the Leghorn, the Spanish, the Friesland runt, &c. The *columba domestica Pifarum, Hispaniæ, et Frisiz*, of Moore.

The Leghorn runt is a stately large pigeon, seven inches or better in the legs, close-feathered, and fast fleshed, extremely broad-breasted, and very short in the back. He carries his tail, when he walks, somewhat turned up like a duck's; his neck is longer than any other pigeon's, and he carries it bending, like a goose or swan; he is goose-headed, and his eye lies hollow in his head, with a thin skin round it, like that of the Dutch tumbler; his beak is very short for so large a bird, and has a small wattle on it, and the upper chap falls a little over. It is a very valuable pigeon, but is tender, and requires care.

The Spanish runt is the longest bodied of all the pigeons; it is short-legged and loose-feathered, and does not walk upright as the Leghorn runt. These are of a great variety of colours, but are apt to have accidents in sitting, from their sitting too heavy, and often breaking their eggs.

The Friesland runt is a large pigeon, and has all its feathers reverted, or looking as if placed the wrong way.

The Roman runt is a pigeon of the same general make with the common kind, but so large and heavy, that it can hardly fly.

The Smyrna runt is middle-sized, and is feather-footed, and that to such a degree sometimes, as to look as if there were wings upon the feet; the feathers of these are sometimes four or five inches long, and often pull the eggs and young out of the nests.

The common runt is the common blue pigeon, kept for the table, and known to every body. Moore's *Columb.* p. 42. See PIGEON.

RUNT is also a name given to Canary-birds, when three years old. See CANARY-BIRD.

RUNT, in *Rural Economy*, a name given to a small kind of black cattle brought from Wales and Scotland.

But though this term be most usually applied to the small cattle of Wales and Scotland, it is not unfrequently employed in describing the properties and qualities of the smaller, and mixed English breeds, especially those which have a stiff compact, runt-like appearance, and which, in their feeding and their habits, have considerable resemblance to them. This sort of cattle stock is often very suitable for grazing farmers, in districts where the pastures are of the inferior kinds, and for feeding out on the artificial grass-pastures, where a large flock is wanted which will soon become fit for the butcher.

RUPALA, in *Botany*, Willd. Sp. Pl. v. 2. 536. Mart. Mill. Dict. v. 4. See RHOPALA and ROUPALA.

RUPAS, in *Geography*, a town of Hindoostan, in Bahar; 18 miles S. of Hajypour.

RUPEE, ROUPIE, or *Roupies*, in *Commerce*, a money of account, and also a coin in various parts of the East Indies. During the prevalence of the Mogul power in Hindoostan, one principal coin, denominated the "sica rupee," was every where current: it was of a determinate weight, called the "sica," which served as a standard for other weights. The principal piece of gold was the "Mouir," which was of the same weight as the sica rupee; and both were intentionally minted without any alloy. The same denominations of money are still current in India; but they differ from each other, and have deviated from their original purity.

The East India Company have adhered to it as nearly as possible; but the monies of some of the native princes, which are of a high degree of fineness, are subject to frequent alterations; so that assayers and money-brokers, under the appellations of "shroffs," are appointed to set a value upon the different coins that are offered in payment.

The principal money of account in India is the "current rupee," to which real coins are reduced before they are entered into books of accounts. This reduction is performed by adding to the species a certain per-centage, called the "Batta," and varying according to the value of the coins, and also to the rate of exchange.

In Bengal, or Calcutta, accounts are kept in current rupees; each rupee being divided into 16 annas, and each anna into 12 pice. The East India Company, however, keep their accounts in sicca rupees, annas, and pice, which bear a batta of 16 per cent. against current rupees, annas, and pice; and in their public and financial statements, which are submitted to parliament, each sum of sicca rupees is reduced to current rupees, by adding to it this batta; and the current rupee is then reckoned at 2s. sterling. The Bengal coins, struck at the Calcutta mint, are sicca rupees, called also silver rupees, and gold mohurs, sometimes called gold rupees; 16 of the former being, by regulation, 10 paise for one of the latter. Thirty-two punns, or 2560 cowries, are generally reckoned for a current rupee; but the value of cowries fluctuates, nor are they considered as a legal tender above the value of 1 anna piece, without mutual consent of parties. A lack of rupees is a sum of 100,000, and a crore is 100 lacks, or 10,000,000 of rupees.

The sicca rupee is to weigh 1 sicca, corresponding to 179½ English grains, and to be 11 oz. 15 dwt. fine; thus it should contain 175.927 grains of fine silver, and its value is 24½d. sterling, or, more accurately, 24.566d. These rupees were formerly called sicca, only during the first year after their coinage, when the batta they bore on current rupees was 16 per cent.; the second year this was reduced to 13; and the third and following years, the batta was 11 per cent. They were then called "sonaut" or "sunat" rupees. But by way of abolishing this distinction, all the rupees coined of late years by the East India Company have been dated the 19th Jun, that is, the 19th year of the Mogul emperor's reign; and thus all the rupees of the above weight and fineness are considered of equal value, in whatever year they may have been coined.

According to these regulations, the current rupee is worth 21.177d., valuing silver according to the mint price in England; but the market price in India is generally much higher, making this rupee worth 2s. nearly, and the sicca rupee about 2s. 6d. In the Company's books, 243 current rupees are valued at 100 dollars.

In the upper provinces of Bengal, there is another rupee, struck at the Ferruckabad mint, which weighs 173 grains, and contains 165.215 grains of pure silver; and therefore its sterling value is 23d. nearly.

The silver coins at Madras or Fort St. George are "Arcot" rupees. Each of these weighs 176.4 grains, and contains 166.477 grains of fine silver; and therefore its sterling value is 23¼d. It is divided into 12 annas and 192 pice, like the other rupees.

At Bombay accounts are kept in rupees; each rupee being divided into four quarters, and each quarter into 100 reas. The rupee is also divided into 16 annas. An urdee is two reas; a doreca, 6 reas; a dooganey, or single pice, 4 reas; a fuddea, or double pice, 8 reas. A paunchea is 5 rupees, and a gold mohur, 15 rupees. The annas and reas are only imaginary monies.

The coins of Bombay are the mohur, or gold rupee; the

silver rupee and its half; also the double and single pice, the urdee, and doreca, which are copper coins, with a mixture of tin or lead. The old Bombay rupee was the same as that formerly coined at Surat under the Mogul: it weighed 178.314 English grains, and contained 1.24 per cent. of alloy. It was agreed that both should circulate at an equal value, and the coin be kept to its exact standard of weight and fineness. At length, in 1800, the Company found it expedient to order the Surat rupee, which had been debased by an augmentation of alloy, to be struck at Bombay; and since that period, the rupees of both places have been kept at an equal value, weighing 179 English grains, and containing 164.74 grains of fine silver, which answer to 11 oz. 1 dwt. fine; and thus they are worth 23d. sterling.

In the Company's financial accounts, which are submitted to parliament, the Bombay rupee is reckoned at 2s. 3d., and then it bears a batta of 16 per cent. against current rupees, though in the tables the batta is stated at 10 per cent. It was settled in 1800 that the mohur should be of the same weight and fineness as the silver rupee, and that it should pass for 15 such rupees.

At Anjengo, on the Malabar coast, a silver rupee is worth, 7 old fanams, or 6 new ones, called gallon fanams: the fanam is 12 pice, or 16 vis; and a pice 4 budgerooks: all these are real coins. In the Company's accounts, an Anjengo fanam is reckoned to be worth ¾ths of a Calicut fanam, or ¼th of a Surat rupee, which gives its intrinsic value about 4¾d. sterling. At Calicut, 5 fanams are commonly reckoned for one rupee. The fanam is a small gold coin, with a considerable alloy of silver and copper, and the tar (¼th of the fanam) is a small silver coin. The Calicut fanams have been found, by assays made at Bombay, to contain 52½ parts of gold, 29 of silver, and 17½ of copper. They are worth 6d. sterling. At Cambay, on the Malabar coast, accounts are kept in rupees of 48 pezas. The rupee is worth about 2s. sterling. A Venetian sequin passes here for 5 rupees; a Persian abassi for 1¼ rupee; and a Persian mamoodi for 24 pezas. At Cochin, accounts are kept in rupees of 16 annas. These are reckoned of equal value to the Surat rupees. Accounts are also kept in fanams, 20 of which are generally reckoned for a rupee.

At Mangalore, accounts are generally kept in sultanny pagodas, rupees, and annas; the pagoda being 4 rupees, and the rupee 16 annas. At Masulipatam, accounts are kept in pagodas, rupees, and annas. The pagoda is 3½ silver rupees, and the rupee 16 annas. The coins are gold rupees, weighing 171¼ English grains, about 23¾ carats fine, and worth 1l. 10s. sterling; pagodas of nearly the value of the star pagoda of Madras; and silver rupees, 24¼ of which weigh a feer, or 4293 English grains, and the fineness of these rupees is 11 oz. 12½ dwt. The value is, therefore, 23½d. sterling.

The coins of the Myfore country are gold mohurs, passing for 4 pagodas; sultanny pagodas, and other pagodas, all passing for 13 fanams; and also sultanny fanams and cantery fanams, two small gold coins of base alloy. Also sultanny rupees, and rajah rupees, 26 of which pass for 7 sultanny pagodas; copper dudos, called by the English dubs: 260 dudos are the market price for a sultanny pagoda. The shroffs, in exchanging copper for gold or silver, pay at the rate of 234 dudos for a pagoda; but in changing gold and silver for copper, they receive 240; whilst the price fixed by government is 182 dudos per pagoda. The sultanny rupee weighs 177 grains, and is 11 oz. 5½ dwt. fine; and is therefore worth 23¼d. sterling nearly.

At Pondicherry, accounts are kept in pagodas of 24 fanams, and the fanam is subdivided into 60 cash. The coins are gold pagodas, and silver rupees and fanams, mentioned

# RUPEE.

under Madras rupee; also copper cashes, and dudus, a copper coin, 20 of which are reckoned to a fanam. Gold and silver are weighed by the feer, pagoda, rupee, and fanam. A feer weighs  $24\frac{1}{2}$  rupees,  $81\frac{1}{4}$  pagodas, or  $731\frac{1}{4}$  fanams. A rupee weight equals 30 fanams, or 480 nellos; a pagoda weight, 9 fanams, or 144 nellos. Thus 3 rupees are equal in weight to 10 pagodas.

At Scindy, the coins current are silver rupees of 16 annas, or 48 copper pice. At Surat, accounts are kept in rupees of 16 annas, or 64 pice. The coins are mohurs or gold rupees, and silver rupees, with halves and quarters.

A gold rupee passes for 15 silver rupees. Here are also pezas or pice, of copper or lead, 64 of which are reckoned to one silver rupee. See the coins under Bombay, *supra*.

At Tranquebar, accounts are kept in rixdollars of 12 fanams, and also in rupees of 8 fanams; and the fanam is divided into 80 cash. The coins are silver rupees, double and single fanams, and copper dudus or cash. Rupees are here coined under such regulations, that 1302 of them are worth 600 old Spanish dollars, weighing 43 lb. 7 oz. 2 dwt. troy. The value of the Tranquebar rupee is therefore  $24\frac{1}{8}d$ . sterling.

The following Table shews the Affay and Value of Rupees.

	Affay.		Weight.		Contents in pure Silver.	Value in Sterling.	
	oz.	dwt.	dwt.	gr.		grains.	s.

## RUPEE.

The inscriptions on the silver coins of the East Indies are as follow :

The sicca rupee has the legends nearly the same as on the mohur, and may be thus translated: "Struck in the seven climates (date of the Hegira), by the shadow of God's favour, Shah Allum king, disciple in the faith of Mahomet;" and on the other side, "Struck at (name of the place), in the 19th year of the august and glorious reign of the emperor," &c. Some rupees do not bear the date of the Hegira, but only that of the emperor's reign; and all the rupees struck in Bengal of late years, at the Company's mints, have been dated the 19th year of his reign, as above.

The Arcot rupee has on one side, "Blessed coin of the conquering king" (the name); on the other side, "Struck at Arcot in the year — of the reign," and the date of the Hegira. But it may be observed, that in these and many other rupees, except such as are coined by the East India Company, the legends are often illegible, owing to the edge being chipt or worn, or to the piece being too small to receive the impression.

The rupee of the Dutch East India Company has on one side, "Coin of the company of Holland," and the date of the Christian era; on the other side, "In the great island of Java."

The sultany rupee of Tippoo bears the same impressions and legends nearly as Tippoo's mohur.

The rupee of Persia, or piece of 10 mamoodies, has various legends. Some bear the sovereign's name, as "Sultan Shahrokh;" and on the other side, "May God prolong his reign, coined at" (the name of the place and date of the Hegira). On other rupees, the king of Persia styles himself "The servant of the monarch," that is, of the Iman Riza, the head of their religion, whom the Persians consider as the real sovereign of their empire; and the coins are often struck in the name of the Iman Riza, with this legend, "By the divine decree, the coin of happy omen has been struck in the name of Ally Riza, son of Mufa;" and on the other side, "There is no God but God, Mahomet is the apostle of God, Ally is the favourite of God, struck at —," with the date of the Hegira.

The silver fanam of Pondicherry bears on one side several flower de luces; and on the other, various flowers, dots, and lines, without any inscription.

The larin is a silver wire about half an inch in length, doubled up, and flattened on one side to receive the impressions of some characters. It was first made in Arabia, and has become scarce, but is still used as money of account.

The mohur, or gold rupee, (coined under the reign of the emperor Shah Allum, which began in 1770,) has on one side, "He who is the shadow of God's favour, the protector of the religion of Mahomet, the emperor Shah Allum, coins money for the seven climates," with the date of the Hegira; on the other side, "Struck at — the year — from the happy accession." Some mohurs have only, on one side, "Coin of the emperor Shah Allum," with the date of the Hegira; and on the other, the year of the reign. The coins struck by the East India Company bear the name of the Mogul emperor; and those minted of late years are dated the 19th year of the emperor's reign, and the number 19 is visible on some part of the piece.

The mohur of Tippoo has on one side, "The faith of Mahomet, the most excellent in this world, is supported by the splendour of the victories of Hyder. Hyder! exalted in equity; struck at Seringapatam, the year pre-eminent in prosperity," with the date of the Hegira. On the other

side, "He alone is the equitable sultan; the epoch of the accession was a year of happy omen," with the date of the reign. Some of Tippoo's coins are dated according to an Indian era, which is divided into cycles of 60 years each; of which cycles 81 are supposed to be now elapsed.

The faruki, or quarter mohur of Tippoo, has on one side, "Mahomet, he is the only and right sultan," with the date; and on the other side, "Faruki, struck at Patan" (Seringapatam), with the date of Tippoo's reign, and a Persian H, the initial of Hyder.

The zodiacal rupees are pieces of twelve different impressions, representing the twelve signs of the zodiac. They were coined between the years 1616 and 1624 of the Christian era, by Jehangeer, and have been long out of circulation. They are, however, much sought after, and highly valued as objects of curiosity. Each sign, or figure, is surrounded by rays representing the sun; and on the reverse is the following inscription: "This ornamented coin in Agra found its face (received its impression) in the year — from the sovereign Jehangeer, son of king Akber."

The zodiacal rupees are exceptions to the Mahometan law, which forbids the representation or embossment of figures; but it is said that Jehangeer had little respect for his religion; and it is further stated by some writers, that his favourite queen, Nur Mahal, had obtained permission to reign for one day, (others say for one year,) and that she caused these coins to be struck, to perpetuate the memory of her short reign. This account, however, cannot be quite correct, as the dates of these rupees are different.

We shall here add, that, in the business of exchange, London draws on Bengal in current rupees at 2s. more or less, or in sicca rupees at 16 *per cent.* above current; also on Madras in pagodas at 7s. 6d. more or less; and on Bombay in rupees at 2s. 2d. more or less.

Such bills are mostly at 60 or 90 days sight: but bills from those places on London are generally drawn at 6, 9, or 12 months sight; in which case, the sicca rupee is valued at 2s. 6d., the pagoda at 8s., and the Bombay rupee at 2s. 4d. sterling, more or less.

The bank of Bengal has been incorporated by a charter for seven years, granted under the governor-general in council, by virtue of the authority vested in him by the act of the 47th of George III. sec. 2. cap. 28.

The capital of the bank is 5,000,000 sicca rupees, that is, 50 lacs. It is divided into 500 equal shares, 100 of which belong to the government, and the other 400 to individuals.

The business of the bank chiefly consists in issuing notes, keeping cash for others, discounting bills, and granting loans at short periods, for the accommodation of merchants, and the general convenience of the public.

The notes of this bank are issued at sums not less than 10 sicca rupees, and not exceeding 10,000: they are paid off in specie when presented, and are therefore accepted as cash in all transactions, although they have not been declared a legal tender, except in payments to be made to government at their general treasury, and other offices of the presidency; and likewise at the provincial treasuries, but under certain conditions and limitations.

The interest of money in India fluctuates from 8 to 12 *per cent. per annum*, and it has been even higher; but the bank, which engages not to charge above 12, has already lowered the rate of interest, and has in many other respects rendered essential service to trade and commerce. We are indebted for the materials of this article to the excellent work of Dr. Kelly, entitled the "Universal Cambist."

RUPEE, *Gold.* See MOHUR.

RUPELA, in *Geography*, a town of European Turkey, in the Morea; 12 miles S.W. of Corinth.

RUPELLENSIS SALT, *Rochelle Salt*, in *Chemistry*, a name given to a peculiar salt, invented by M. Seignette, apothecary, at Rochelle, and extolled as a very valuable medicine.

The preparation of it was kept a great secret, till Messrs. Boulduc and Geoffroy discovered and published its composition.

To prepare this salt, crystals of marine alkali are to be dissolved in hot water, and into this liquor powdered cream of tartar is to be thrown. When the effervescence ceases, more cream of tartar is to be added, till the liquor is saturated; it is then to be filtered and evaporated; and very fine and large crystals may be obtained by cold, each of which is the half of a polygonous prism cut in the direction of its axis.

The crystallization of this salt, according to M. Baumé, as well as of the vegetable salt, is much more easy and more beautiful, when the liquor, in which it is made, contains an excess of alkali, which does not prevent the salt from being exactly neutral, after it has been well drained.

The salt of Seignette has a saline taste, moderately strong, and disagreeable. It retains much water in its crystallization, is soluble in a less quantity of hot water than of cold water, and becomes farinaceous in a dry air.

This salt is used only in medicine; being a good purgative, when taken from an ounce to an ounce and a half. It is dissolved in pure water, or in pitifans and mineral waters, to render them purgative. It is also given in small doses of one or two drachms, as an alterative, aperitive, and corrector of other purgatives. But, upon the whole, it does not differ much from ordinary soluble tartar. This is now known under the name of "tartrate of potash and soda," &c. &c. See SODA.

RUPERT, *Prince*, in *Biography*, third son of Frederic, elector palatine of the Rhine, and Elizabeth, daughter of James I., and he was, consequently, nephew to king Charles I., was born in the year 1619. His education, like that of most German princes, especially the younger brothers, qualified him for arms, and he was soon discovered to be extremely well fitted in respect to natural abilities, and acquired accomplishments for a great commander. In his thirteenth year he accompanied the prince of Orange to the siege of Rhinberg, and so greatly distinguished himself, that at the age of eighteen he was entrusted with the command of a regiment of cavalry. He was taken prisoner in the following year by the Imperialists, who detained him a considerable time. Having obtained his liberty, upon the ruin of the house-palatine in Germany, he came to England with his brother Maurice in 1642, and offered his services to their relation Charles I., between whom and the parliament, war had just commenced. Through the whole war he behaved with great intrepidity; and on many occasions his exertions were attended with very extraordinary success. Almost at the outset of the business he was placed at the head of a body of horse, with which he immediately routed a part of lord Essex's cavalry, and established his character for spirit and enterprise. At the

subsequent fight at Edge-Hill he commanded the right wing of the royalists, with which he drove out of the field the parliament horse; but, by an incautious pursuit, the king's infantry were left exposed, and suffered severely, so that the result was a drawn battle. In the next he proceeded into the west to join the Cornish royalists: and afterwards he undertook the siege of Bristol, which city he carried by assault. He was present at the battle of Newbery, where he broke the enemy's horse; but was repulsed in his charge on their foot. The king, on account of his great services, advanced him to the dignity of a peer of England, by the title of earl of Holderness, and duke of Cumberland. In 1644 he relieved Newark, besieged by the parliamentarians; after which, having collected a considerable force, he marched against the earl of Manchester, then investing York, and made a junction with the marquis of Newcastle. Contrary to the advice of that nobleman, he engaged the parliament army in a pitched battle at Marston-Moor, and placed himself in the right wing. He was there opposed by Cromwell, and in the conflict prince Rupert's cavalry was put to flight. The final issue was a defeat of the royalists, which was, in fact, the commencement of the misfortunes that thenceforth attended the king's arms. In this action the courage of prince Rupert was signally displayed; but his precipitation, and want of attention to the marquis of Newcastle, were very much censured; he, however, redeemed his character by some spirited services which he performed between this and the battle of Naseby, in which he took a most distinguished part. He commanded in the right wing; and by the impetuosity of his charge he defeated the parliament's left, under the command of Ireton; but committing his usual fault of pursuing inconsiderately, the battle was lost before he could return to restore order. After this event, he withdrew towards the west, and threw himself into the city of Bristol. That important place, thus garrisoned, was expected to make a vigorous defence; but the prince seems to have lost himself on this occasion, and surrendered the city to Fairfax before a close attack was made. The king was so indignant at his conduct, that he recalled all his commissions, informing him he could thenceforward dispense with his services.

When a part of the English navy, in 1648, went over to Charles II., it was placed under the command of prince Rupert, who attempted, in vain, the relief of some maritime towns and fortresses, attacked by the republicans. He then carried on a predatory war, by which the English trade in the western seas was so much annoyed, that admiral Blake was sent with a squadron in pursuit of him. He took shelter in Kinfales, whence he escaped to Portugal, and was protected from his pursuer. He, however, lost a great part of his fleet on the coast of Spain, and with the remainder sailed to the West India islands, where, for some time, he supported himself by making prizes of Spanish and English ships. His brother, prince Maurice, who commanded a separate squadron, being shipwrecked among the islands, Rupert sailed to France, where he disposed of his prizes and ships, and joined Charles at the French court. Between this period and the restoration he occupied himself with those studies which afterwards rendered him celebrated in the annals of science, and to which we shall have occasion to refer at the conclusion of this article.

On the king's restoration, prince Rupert was invited into England, where the king, who had a sincere affection for him, gave him various offices worthy of his high birth. In 1666 the king entrusted him, in conjunction with the earl of Albemarle, to command the fleet, and he soon manifested

all the great qualities that could be desired in an admiral ; for, by his happy return to the fleet, he wrested from the Dutch the only victory they had the appearance of gaining, and, afterwards, on the 24th of June, beat them effectually, pursued them to their own coast, blocked up their harbours, and made them fully sensible of the superiority of English courage when not oppressed by numbers. In the autumn of the same year, having the sole command of the fleet, and learning that the Dutch were endeavouring to join a French squadron of forty sail under the duke of Beaufort, he followed them so closely into the Boulogne road, that, to avoid a battle, they hauled so near the shore, as in all probability they must either have been sunk or burnt, if a sudden storm had not forced the prince to return to St. Helen's bay.

On the prince's return home he was kindly received by the king, and grew into high esteem with the nation. The Dutch war was again renewed in 1673, the French being at this time in alliance with the English. Prince Rupert was appointed admiral of the English fleet, having under him sir Edward Spragge, and the earl of Ossory. Two indecisive actions ensued in May and June, and prince Rupert, whose bravery could not be doubted, was suspected, probably without reason, of being disinclined to the favourite political schemes of assisting the French to ruin the Dutch, and of augmenting the royal authority at home. On his part he complained that he was ill supplied with necessary articles by the admiralty, which was under the controul of the duke of York. To prove the fact, he, without particular orders, returned home, immediately after the battle of the 5th of June, and had address enough to persuade the king to come and examine the state of the fleet with his own eyes. This put the matter beyond all cavil and dispute, and obtained the necessary supplies without any delay, and as he had shewn his spirit by appealing to the senses of his majesty, so he gave as signal a proof of his activity and enterprise, by carrying the whole fleet through the Narrow seas on the 19th of July, and appearing on the Dutch coast, almost as soon as they had received certain intelligence of his returning to his own. In the following August, however, an engagement took place off the Texel, in which the two maritime rivals displayed all the obstinate valour that had rendered their former contests so memorable in naval history, and of which a full and most interesting account will be found in Campbell's Lives of the Admirals, vol. ii. ed. 1813. Prince Rupert was personally opposed to De Ruyter, and by the greatest exertions he disengaged his squadron from numerous assailants, and came to the relief of that of sir Edward Spragge, which had lost its brave commander. (See SPRAGGE.) The French kept aloof, and both sides claimed the victory. This was the close of prince Rupert's warlike services.

On his return from the command, the king expressed some coolness, which was owing, not more to the arts of his highness's enemies, than to the quickness of his letter, in which he gave an account of this last fight, the contents of which a contemporary historian gives in the following words. " In the midst of so many intrigues of opposition here at home, so many delays of his commission, so few powers contained in it, such scanty number of seamen, so little assurance of divers chief commanders, such failure of provisions ; such want of ammunition, and all other necessities, such deceit of navy officers, such non-observance of orders at sea, amongst his own English, and so many manifest defections of the French, not to be staggered in his resolution, nor to be put out of all patience and prudence in action, nor to abate of his affection and zeal for the

honour and service of his majesty, the safe-guard and interest of religion and the kingdom ; in a season when so many Popish projectors played a game under board, and above too ; will be an everlasting argument of his highness's valour and renown, and must needs be a strong obligation upon the king, the parliament, and the people of England, who are now left to judge, whether it was not a wonderful good providence of God, or one of the most memorable pieces of service ever done at sea, to surmount all those difficulties, and even envy itself ; and, after all, to bring home the fleet royal of England, without the loss of one man of war, to her own shore in safety, in despite of all enemies that designed otherwise by sea and land."

But the king's displeasure was not lasting, and he was soon replaced in his favour. After this, prince Rupert led a quiet and, in a great measure, a retired life, mostly at Windsor castle, of which he was governor, and spent a great part of his time in the prosecution of chemical and philosophical experiments, as well as the practice of mechanic arts, for which he was very famous. He is mentioned by foreign authors with applause for his skill in painting, and celebrated by one of the most judicious of our own, for his invention of mezzotint prints, since risen, from their softness and beauty, into so high esteem. He likewise delighted in making locks for fire-arms, and was the inventor of a composition called, from him, Prince's metal. He communicated to the Royal Society his improvements upon gunpowder, by refining the several ingredients, and making it more carefully ; which, as appears upon several trials reported to that learned body, augmented its force, in comparison of ordinary powder, in the proportion of ten to one, an invention which, though too expensive for common occasions, deserves to be remembered, because, in particular cases, it may be of singular utility. He also acquainted them with an engine he had contrived for raising water, and sent them an instrument, of which he made use, to cast any platform into perspective, and for which they deputed a select committee of their members to return him their thanks. He was the inventor of a gun for discharging several bullets with the utmost speed, facility, and safety, which was generally and justly admired. The Royal Society received likewise from his highness the intimation of a certain method of blowing up rocks in mines, and other subterraneous places. The very ingenious and indefatigable Dr. Hooke has preserved another invention of his for making hail-shot of all sizes. He devised a particular kind of screw, by the means of which, observations taken by a quadrant at sea were secured from receiving any alteration by the unsteadiness of the observer's hand, or through the motion of the ship. It was said that he had also, among other secrets, one that was very curious, and, if preserved, might be very beneficial, which was that of melting or running black lead, like a metal, into a mould, and reducing it back again into its original form.

As to his public character in the last ten years of his life, it was that of a patriot, which was owing to the innate honesty of his temper, and not to his having any liking to intrigues. He gave indefatigable attention to whatever appeared to him conducive to the public good. He was a great promoter of the trade to Africa, and a principal protector of the Royal African Company ; as a proof of which, before the first Dutch war in this reign, he offered his majesty to sail with a squadron to the coast of Guinea, in order to vindicate the honour of the crown, assert the just rights of the company, and redress the injuries done to the nation ; but the king, unwilling to hazard his person at such a distance, and in so sickly a climate, though he received the motion kindly, would not consent to it, but contented himself

self with taking an officer of his recommendation (captain Holmes), under whom the squadron was sent. He was an active member of the council of trade. It was owing to his solicitations, after being at great expence, not only in the inquiry into the value, but in sending ships thither, that the Hudson's Bay Company was erected, of which he was the first governor appointed by the charter. In memory of him, a considerable opening on the east side of that bay, in Terra de Labrador, is called Rupert's river. In general, his highness was a great friend to seamen, and to all learned, ingenious, and public-spirited persons, and assisted them with his purse, as well as afforded them his countenance. He was concerned in the patent for annealed cannon, in a glass-house, and other undertakings for acquiring or improving manufactures, for which some have censured him, as giving encouragement to projectors. But surely this censure is very ill placed, since, without such patrons, industry and ingenuity would want support, and many useful inventions, many valuable discoveries, barely emerge, and then sink again into oblivion. But strict justice has been done to his highness's many virtues, and amiable qualities, by abler and more impartial judges, especially in that excellent character of him by the elegant pen of bishop Sprat. In respect to his private life, he was so just, so beneficent, so courteous, that his memory remained dear to all who knew him. This, observes Campbell, I say of my own knowledge; having often heard old people in Berkshire speak in raptures of prince Rupert.

He died at his house in Spring-Gardens, on the 29th of November 1682, in his grand climacteric, leaving behind him a natural son, usually called Dudley Rupert, by a daughter of Henry Bard viscount Bellemont, though styled in his father's last will and testament Dudley Bard. He received the first tincture of letters at Eton school, where the gentleness of his temper, and the modesty and amiableness of his behaviour, procured him universal esteem. His genius, however, inclining rather to arms than study, he was placed under the care of that celebrated mathematician sir Jonas Moore at the Tower. Here he continued till the demise of that prince, when he made a tour into Germany to take possession of a considerable fortune which had been bequeathed to him. He was very kindly received by the Palatine family, to whom he had the honour of being so nearly allied. In 1686 he made a campaign in Hungary, and distinguished himself at the siege of Buda, where he had the misfortune to lose his life, in the month of July or August, in a desperate attempt made by some English gentlemen upon the fortifications of that city, in the 20th year of his age, and, though so young, he had signalized his courage in such an extraordinary manner, that his death was exceedingly regretted. Hume. Campbell's Lives of the Admirals.

RUPERT, in *Geography*, the north-westernmost township of Bennington county, in the state of Vermont, America, containing 1630 inhabitants; 20 miles N. of Bennington.

RUPERT'S Bay, a bay on the N.W. coast of the island of Dominica, which is deep, capacious, and sandy, and affords good shelter from the winds. It is the principal bay of the island, and on it is erected the town of Portsmouth. N. lat.  $15^{\circ} 40'$ . W. long.  $61^{\circ} 18'$ .

RUPERT'S Fort, lies at the bottom of Hudson's bay, in North America, situated on a river of the same name, on the E. side of James's bay, between Slade river N., and Nordway river S. N. lat.  $51^{\circ} 50'$ . W. long.  $80^{\circ} 5'$ .—Also, a fort on the W. coast of the island of Barbadoes; 1 mile N. of Speight's town.

RUPERT'S Head, a cape on the W. coast of the island of Dominica. N. lat.  $15^{\circ} 41'$ . W. long.  $61^{\circ} 19'$ .

RUPERT'S Island, the most westerly of four islands in the straits of Magellan, forming the S. side of Royal Reach; 3 miles S. of Passage Point.

RUPERT'S River, a river of North America, which runs from lake Mistassin into James's bay, Hudson's bay. N. lat.  $51^{\circ} 28'$ . W. long.  $78^{\circ} 56'$ .

RUPERT'S Drops, *lacryme Batavica*, a sort of glass drops with long and slender tails, which burst to pieces on the breaking off those tails in any part, said to have been invented by prince Rupert, and therefore called after his name.

The history of these drops is this: they were first brought into England by prince Rupert out of Germany, and shewn to king Charles II. who communicated them to the Royal Society at Gresham College; and a committee, appointed on this occasion by the society, gave the following account of them. They must be made of green glass well refined, for till the metal, as the glass-men call it, is perfectly refined, they never succeed if made of it; but always crack and break soon after they are dropped into the water.

The best way of making them is to take up some of the metal out of the pot upon the end of an iron rod, and immediately let it drop into cold water, and there lie till it is cold. If the metal be too hot when it is dropped into the water, the business does not succeed, but the drop frosts and cracks all over, and falls to pieces in the water, and every one that does not crack in the water, but lies in it whole till it is quite cool, is sure to be good. There is great nicety in the hitting a due degree of heat in the metal, and the workmen who best know their business cannot promise before hand which shall succeed, but often two fail for one that hits right. Some of them frost over the surface without falling to pieces, and others break into pieces before the red heat is quite over, and that with a small noise; others break soon after the red heat is over and make a great noise, and some neither break nor crack till they seem to be quite cold; and others hold together while they are in the water, but fly to pieces with a smart noise when they are taken out of it; some do this on the instant, others an hour or two after, and others will keep several days, nay weeks, and at last fall to pieces without being touched.

These drops, thus formed, are so hard, that they will bear smart blows of a hammer, on the rounded end, without breaking; and yet if you grind the surface, or break off the tip of the tail, they will shatter, with a loud report, into powder; and in an exhausted receiver, with greater impetuosity than in the open air, and into a finer powder, exhibiting light, when the experiment is made in the dark. But if the drops are ground with powder of emery and oil, or annealed by the fire, they will escape breaking.

This surprising phenomenon is supposed to arise from hence; that while the glass is in fusion, or in a melted state, the particles of it are in a state of repulsion; but being dropped into cold water, it so condenses the particles in the external parts of their superficies, that they are thereby reduced within the power of each other's attraction, and by that means they form a sort of hard case, which keeps confined the before-mentioned particles in their repulsive state; but when this outer case is broke by the breaking off the tail of the drop, the said confined particles have then liberty to exert their force, which they do by bursting the body of the drop, and reducing it to a very peculiar form of powder. See a paper on the phenomena and explication of these glass-drops, by Dr. Le Cat, in the *Philos. Transf.* vol. xlvii. p. 175, &c. See *Annealing of GLASS*.

RUPERTSDORF, HOHEN, in *Geography*, a town of Austria; five miles S.W. of Zisterdorf.

RUPICAPRA, in *Zoology*, a species of antelope. See CHAMOIS. See also OVIS *Annon*.

RUPICHERADT, in *Geography*, a town of the duchy of Berg; four miles N.E. of Blankenberg.

RUPINIA, in *Botany*, from *rupes*, a rock, alluding to its place of growth, is a name given in the Supplement of Linnæus to what Forster had called *Aitonia*, after the celebrated curator of Kew garden; there being another *Aitonia* in that same work. Mr. Dickson discovered, by examining original specimens, that Forster's plant is no other than *Marchantia hemispherica*, without fructification; the supposed *anthers* being nothing but the hairs of the leaf!

RUPITANI, a name given to the Donatists. See CAM-PITE.

RUPOLY, in *Geography*, a town of Bengal; 22 miles W. of Purneah.

RUPPAN, a town of Bohemia, in the circle of Pilsen; 17 miles S. of Pilsen.

RUPPE, a town of France, in the department of the Vosges; eight miles N. of Neufchateau.

RUPPEL, a river of France, formed by the union of the Senne, the Demer, and the Dyle, which joins the Scheldt at Rupelmonde.

RUPPERTSGRUN, a town of Saxony, in the Vogtland; six miles N. of Plauen.

RUPPIA, in *Botany*, was named by Linnæus, in memory of Henry Bernard Ruppianus, native of Giessen, a student of physic, who soon gave up that and every other pursuit for botany. Haller characterizes him as "of short robust stature, with the eyes of a lynx, unwearied limbs, a penetrating genius, and most tenacious memory." He travelled through various parts of Germany, living with the mountain cottagers, disdaining every indulgence, except the study of plants. He seems to have died at an early age. The first edition of the *Flora Jenensis*, compiled from his papers, and arranged after the system of Rivinus, which he much approved, was published in 1718, by J. H. Schutte. Another came forth in 1726; and a third, under the care of Haller, with beautiful plates, in 1745. Each makes an octavo volume.—Linn. Gen. 68. Schreb. 92. Willd. Sp. Pl. v. 1. 717. Mart. Mill. Dict. v. 4. Ait. Hort. Hew. v. 1. 281. Pursh 121. Sm. Fl. Brit. 198. Prodr. Fl. Græc. Sibth. v. 1. 109. Juff. 19. Lamarck Illustr. t. 90. Gært. t. 84. (Buccaferrea; Mich. Gen. 72. t. 35.)—Clas and order, *Tetrandria Tetragynia*. Nat. Ord. *Inundata*, Linn. *Naiades*; Juff.

Gen. Ch. Cal. Perianth none. Cor. none. Stam. Filaments none; anthers four, sessile, equal, roundish, of two roundish valves, bursting transversely. Pist. Germens four or five, nearly ovate, crowded close together; styles none; stigmas obtuse. Peric. none. Seeds four or five, ovate, oblique, each elevated on a long slender stalk, and terminated by the permanent, flat, orbicular stigma.

Ess. Ch. Calyx none. Corolla none. Seeds four, on long footstalks.

1. *R. maritima*. Sea Ruppia. Linn. Sp. Pl. 184. Willd. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 136. Lightf. Scot. 124. t. 8. f. 1. (Potamogiton maritimum, gramineis longioribus foliis, fructu ferè umbellato; Raii Syn. 134. t. 6. f. 1. Fucus ferulaceus; Ger. Em. 1573. Buccaferrea maritima, foliis acutissimis; Mich. Gen. 72; as well as fol. minus acutis; ibid. t. 35.)—Native of salt-water ditches, in most parts of Britain, flowering in July, and ripening seed in August. Dr. Sibthorp observed it in Cyprus, as well as on the classic shore of Argos. Mr. Pursh says it

occurs about the mouths of most rivers in America. The habit of the plant agrees with POTAMOGETON; see that article. The root is probably annual. Stems capillary, very much branched, clothed with alternate, linear, more or less pointed leaves, which embrace the stem with a membranous united stipula. Flower-stalks axillary, solitary, simple, variable in length, according to the depth of the water in which the herb grows, and often spiral, accommodating itself to any alteration, that the flowers, which stand two together at the top, one a little above the other, may not be spoiled by immersion. The plant is most distinguishable when in fruit, by means of the singularly stalked, and as it were umbellate, seeds. Dillenius, in his edition of Ray's *Synopsis*, greatly errs in reporting that the flowers, or stamens, grow remote from the fruit, and that the latter appears first.

Labillardiere, in his account of the plants of New Holland, v. 2. 116. t. 264, describes a *Ruppia antarctica*, whose genus he merely conjectured, having seen nothing of the fructification. This is referred, perhaps more properly, though likewise from the habit only, by Mr. Brown, to Decandolle's genus *Caulinia*; see Br. Prodr. Nov. Holl. v. 1. 339.

RUPPIN, NEW, in *Geography*, a town of the Middle Mark of Brandenburg, the capital of a county or circle of the same name, containing two Lutheran churches, and 800 burghers. It is situated on a large lake, formed by the river Rhine, and has considerable manufactures of cloth. "Old Ruppin" is situated on the same lake, opposite to New Ruppin; 30 miles N.N.W. of Berlin. N. lat. 52° 55'. E. long. 12° 55'.

RUPPOLI, a mountain of Etruria; 10 miles S.W. of Florence.

RUPRECHTSHOFEN, a town of Austria; 12 miles S.E. of Ips.

RUPSTA, a town of Sweden, in East Gothland; six miles W. of Linköping.

RUPTORIUM, in *Surgery*, a caustic applied with a view of opening an abscess.

RUPTURE. See HERNIA.

RUPTURE-IVort, in *Botany*. See HERNIARIA.

Although there be no foundation for the virtues ascribed to this plant, and implied in its name in the curing of ruptures; yet there is another case in which German physicians strongly recommend it. It is in the disorder of the eyes which is brought on by reading or writing by candle-light, or by examining nice objects, or very fine work. This distemperature seems to be properly a diminution of sight, without any apparent cause, or visible alteration in the eye, and is probably owing to a viscid matter obstructing the optic nerves, and preventing a supply of their proper fluid. The herniaria, being a gentle and mild attenuant, is supposed to be adapted for the relief of this disorder. Gruhman De Novo Caliginis Remedio.

The author gives many instances of the success of this remedy, and mentions two methods of giving it; the one in powder, and the other in tincture: the former way is preferred, and the method is to gather the herb in its prime, and powder it after it has been dried in the shade; then to sprinkle the quantity of a scruple of this powder on the bread and butter used for breakfast. If this is not liked, the tincture is to be made with spirit of wine, as strong as the plant will make it, and forty drops are to be taken every morning and evening in any liquor.

The distemperature this is proposed to cure is very common, yet this is almost the only thing, as it has been said, that has been prescribed by way of remedy, and deserves to be

be fairly tried. But no modern practice seems to warrant the above-mentioned author's recommendation of it.

**RUPUTTY**, in *Geography*, a town of Hindoostan, in Bahar; 12 miles E. of Chuprah. N. lat.  $25^{\circ} 44'$ . E. long.  $85^{\circ} 11'$ .

**RURAL**, or **RUSTIC**, formed of *rus*, *rusis*, *country*, something that relates to the country.

**RURAL Dean**, in the *Ancient Church*. See **DEAN**.

**RURAL Economy**, a term which comprehends the amelioration and improvement of the landed and different other property, habits, and customs of a country, in whatever way or by whatever means of a rural nature they may be capable of being accomplished, as, whether in the laying out, inclosing, and cultivating the ground, or in the management of the different practices, operations, and processes which have a relation to it, or to its produce, the regulation of the various kinds of labour which attends them, as well as that of the sale of the different articles of provisions which are raised from it in the several fairs and markets, and the provision of a variety of substances which are necessary for use as fuel, as well as for many other purposes of the rural kind. In these views, the bettering of the condition of different sorts of land, by the particular modes and practices of husbandry which have been lately discovered, are of very great importance, as well as the improved management in feeding animals, dairying, and making a great number of other articles, and the working of different sorts of quarries and pits for the raising of materials which are useful in various rural intentions, besides those of being consumed as fuel.

There are many other kinds of works, establishments, and constructions which are partly of this nature, and which contribute in no small degree to the general improvement and advantage of a country, such as those of roads, so far as the state, form, and convenience of them are beneficial in this way; the construction of convenient railways for the more ready conveyance of weighty articles of slate, coal, and other kinds of produce; the formation of canals, and the widening and altering of rivers, for the benefit of water-carriage for different bulky matters; and the raising of embankments against the sea, or large rivers, for the better cultivation, protection, and acquisition of land. To which may be added, the establishing of fisheries of different kinds, and improving the management of them, as well as some other undertakings.

The rural habits and practices of a country, which are necessarily either different at different times, in consequence of the changes which are always taking place in the circumstances and conditions of it, or fixed by the hilly and mountainous nature of its surface, are constantly slow in their progress towards the state of amelioration and perfection; on which account, they and the industry of the rural population of a nation ought to be looked upon and considered in respect to what they were formerly at different periods of time, what they are now, and what there is the probability of their becoming by the progress of man in the state of society.

In the infant state of a country, while its riches and resources chiefly consist in the number of herds and flocks which it can support, the attention and exertion of the people are, for the most part, with much propriety, directed to the rearing, feeding, protection, and management of these sorts of live-stock. Afterwards, when the tillage system becomes, in some measure, to be connected and incorporated with the pastoral state, there is a division of their cares and labours, between the cultivation of the soil for the raising of grain, and the attendance on their cattle, flocks, and sheep

flocks. And ultimately, when the benefits and numerous advantages of commerce begin to be known and appreciated, no small part of them leave the cattle and the tillage plan for that of trade, and the manufacturing of different kinds of articles for its use and benefit.

The history of all nations, as well as that of the same nation at different periods of time, furnishes numerous instances in proof of these progressive stages of change in their rural state. It is therefore a great absurdity, as well as error, to stigmatize and reprobate the customs and practices of a people or country, in any one of such stages or changes of their rural means, by the comparison of those of another, as the object of their industry and application is widely different at the different times, and consequently the test by which they ought to be judged of, must be equally different. Thus, the condemnation and reprehension of particular modes, practices, and habits of the rural kind, from preconceived notions peculiar to the situation and way of life in which the persons have been themselves placed, are highly preposterous and foolish, as any one is well employed in pursuing an useful and laudable occupation or undertaking with industry and perseverance, whatever the nature of it may be, whether it be that of tending and managing herds and flocks, or that of conducting some other business, practice, or process, each contributing to the convenience of the community, however different their engagements may be, or the rank which they hold in society.

The practice and custom of attending herds and flocks, which prevailed in a certain stage of society in all countries, was more quickly departed from in cases where the land was suitable for the purposes of tillage than in other instances; but most so on the sea-coasts and the banks of navigable rivers.

Improvements of this nature are always highly deserving the attention and encouragement of the public, on account of the general influence which they have in promoting and bettering the state and condition of society; as they may be said to embrace the introduction of whatever is useful and advantageous, as well as, in some measure, what is ornamental, into a country. These beneficial changes and alterations are accomplished in a great variety of different ways, and by a number of different methods, but principally by the discovery of new means, the cultivation of what has been formerly overlooked or neglected, and by having recourse to superior and more enlightened modes of management in the whole. In this manner a vast increase of produce of different kinds, as well as of national wealth, may be brought forth, and at the same time much ornamental effect and convenience be produced.

**RURAL Architecture**, the nature of any sort of country building, but principally those of the farm or agricultural kind. See **FARM**.

**RURAL Artificers**, all those persons who are employed in the making of any sort of tool, implement, or machinery, for the purpose of agriculture, husbandry, or any other rural art or business. The excellencies or defects of these sorts of workmen depend upon their ingenuity and knowledge of the nature of mechanism in general, or their deficiency in both these respects.

Wherever the construction of machinery has made any considerable progress, there is most commonly a portion of the same spirit diffusing itself among the rural artificers of the same neighbourhood; but where this has not happened, the contrary is always the case. It is, however, of vast importance to the farmer and landed interest in general to be in possession of, or capable of procuring, ingenious and intelligent workmen of this description, as the progress  
and

and advancement of the art of farming greatly depends upon it.

The writer of the Agricultural Report of the County of Middlesex has remarked, that not only the common wheelwrights and smiths of that district have no ideas of machinery, or the capacity of executing any thing from drawings or specifications; but that the generality of the farmer's labourers are equally stupid, and unwilling to execute their work in any way to which they are not accustomed. Hence, it is contended, the difficulty of introducing any thing new in the implements or practice of husbandry is almost insurmountable. Even the most trifling alteration, or deviation from the old system or plan, is resisted, it is said, both by the artificers and labourers; and every possible obstruction thrown in the way of the farmers, to prevent what they deem an innovation on the established custom of the place, or part of the county where it may take place. The same is the case in regard to all the more complex kinds of machinery, as it is asserted that it is absolutely impossible to get a plough, a threshing-mill or machine, a winnowing machine, or indeed any other similar sort of implement of husbandry, constructed on a good principle by the artificers of this county; and that it is not much less difficult to induce the labourers to make use of them, when they are brought from any other place at a distance. Thus the farmer is reduced to the necessity of treading in the steps of his forefathers, though the practice may be at war with his own better judgment and inclination; and many useful alterations and improvements in the art of cultivation retarded and kept back.

But though there may be some expert, ingenious, and sensible mechanics in a district, who are capable, and fully competent to execute orders for all kinds of implements and machinery, which may be useful or necessary to the different purposes of agriculture and husbandry, their exertions and labours are often more considerably lessened in utility and value than might be supposed, on account of the unavoidable wear and tear which they undergo, necessarily subjecting them to frequent repairs, which are utterly impossible to be got done in any skilful manner by the common country artificers; and the great inconvenience, expence, and loss of time, which must be sustained by sending them for such purposes to the original constructors of them, who are not unfrequently at a great distance. This is another great drawback on improvements in the practice of farming.

Mere theoretical cultivators, who have not experienced these difficulties and inconveniences, and are so frequently condemning the whole body of farmers as obstinately resisting every attempt at improvement in the art, often display their own want of knowledge and superficialness on the subject, by bestowing that degree of reprobation and censure on the farmer, which ought to have been applied to his labourers and rural artificers.

The proper encouragement of good and expert rural artificers is consequently a matter which tends greatly towards promoting and bettering the state and condition of agriculture, in various essential points, as well as to augment and render its conveniences much more numerous and beneficial.

*RURAL Buildings and Seats, in Gardening.* See *RE-TREAT* and *SEAT*.

*RURAL Gates, in Ornamental Gardening,* are such as are employed for ornamenting the entrances to country residences, or other similar purposes. They should have a form and construction, so as in some measure to harmonize and accord with the nature and style of the residence to

which they are to belong; the same general principles being, in some degree, applicable here as in the case of rural lodges. It is indeed suggested, that they both present ample scope for invention, which has been productive of two great evils: the first of which is, that too many designs of this nature have been given to the public; and the latter, that the proprietors and other persons have adopted, copied, and executed them, without any regard to the nature of the situation, or the character of the mansion or residence to which they are to be affixed. It is believed that no person will require proofs of this, who has seen any thing of the country. In regard to what relates to economy and utility in gates for common purposes, it may be seen under the head *GATE*.

*RURAL Lodges,* are such adorned small buildings as are necessary for the entrances, or other parts of the approaches or drives of country residences. Those for the former, according to the opinion of Mr. Loudon, should be designed and constructed in a character and on principles somewhat analogous to that of the residence to which they belong; while those of the latter, or for the drives, should seldom be more than improved rural cottages, unless the nature of the situation should suggest some peculiarity of form, or description of them. It is supposed, that the notion of appropriating a country, by stamping all such buildings, as well as some others, with something which may denote the continuation of the proprietor's estate, is only calculated to gratify the vanity and ostentation of such persons. The truly great, it is conceived, need nothing to make them appear so; and in the country, they will ever be more assiduous to render themselves agreeable to their neighbours, than to shew the unfociable disposition of monopolizing territory. In regard to their grounds, it is suggested that they will be ready with Marlborough, Argyle, Howard, and other noble proprietors of grand residences, to say with the marquis of Ermeonville, "This, the farm, only is shut up; the three others, the wood, the forest, and the meadow, are open to every body; and I only wish that they should think themselves as much at home as if they belonged to them." On the whole, those sorts of buildings should always partake somewhat of the nature of the situations, and the styles of building in the residences to which they are to be attached. See *COUNTRY RESIDENCE*.

*RUREMONDE, or ROERMOND,* in *Geography,* a town of France, and principal place of a district, in the department of the Lower Meuse, late of Upper Guelderland, in the Aultrian Netherlands, situated at the conflux of the Roer and Meuse. It derives its name from that of the former river and the term *Mond*, signifying mouth, both expressing its situation at the Mouth of the Roer. It was encompassed with walls and six gates by Otho, furnished the Cripple, 14th count of Guelderland. In 1290 it obtained from Rodolphus the privilege of coming money; and in 1562 it was created into a bishopric by pope Paul IV., under the archbishopric of Malines. The cathedral is the only parish church. Its magistracy is composed of nine echevins and two secretaries. In 1665 an accidental fire destroyed almost all the houses, convents, and the bishop's palaces. It has been often taken and retaken by the Dutch and Spaniards, in their civil wars; 30 miles N. of Aix-la-Chapelle. The town contains 3788, and the canton 14,621 inhabitants, on a territory of 222½ kilometres, in 20 communes. N. lat. 51° 12'. E. long. 5° 50'.

*RUREY,* a town of France, in the department of the Doubs: 4 miles E. of Quingey.

*RURROW,* a town of Hindooistan, in Doobab; 30 miles E. of Etaya.

RUS, a mountain of Arabia, in Yemen; 8 miles S. of Sana.

RUSAZUS, in *Ancient Geography*, a town of Africa, on the coast of Mauritania Cæsariensis, between Rufubirfis and Vabar, according to Ptolemy. Pliny gives to this town the appellation of Colonia Augusta; and in the Itinerary of Antoninus it is named Rufazis Municipium, and placed between Iomnium Municipium and Saldis Colonia.

RUSBACH, in *Geography*, a river of Austria, which runs into the Danube, 2 miles above Hainburg.

RUSBACH, *Hohen*, a town of Austria; 9 miles N. of Korn Neuburg.

RUSCEK, a town of European Turkey, in Bulgaria, on the Danube; in which are 20 mosques, 3 churches, and a Jews' synagogue. It is defended by a castle, with a garriſon; 50 miles E. of Nicopoli. N. lat. 53° 52'. E. long. 25° 15'.

RUSCINO, in *Ancient Geography*, a town of Gallia Narbonensis, the capital of the people called Conſuarani. It was in this town that the people of the country assembled, to deliberate on the passage demanded by Hannibal, according to Livy, lib. xxi. cap. 24. It was a Roman colony, according to Mela; and Pliny says, that it enjoyed the jus Latinum. It was ruined by the Normans, and its name is preserved in Rouffillon. In the Itinerary of Antonine, this town was marked on the route from Narbonne to Castulo, between Combuſta and Ad Centuriones.—Also, a river of Gallia Narbonensis, according to Strabo, who says that it had its source in the Pyrenées, and watered a town of the same name. Ptolemy calls it Rufeio, and places its mouth between those of the Illiberis and Atages.

RUSCINONA, a port of Africa, whither, according to Dr. Shaw, the Carthaginian fleet retired, the night before it engaged with Scipio near Utica. This name is said to be of Phœnician origin; the first part of it, *Rus* or *Ras*, denoting cape; and the latter, *annonna*, expressing the great quantity of corn and provisions that were shipped off from this place. These circumstances lead Shaw to conclude, that Ruscinona is the present "Porto Farina," on the coast of Tunis, called by the inhabitants, from an ancient salt-work near it, "Gar-el-Mailah," i. e. the cave of salt. This port, especially the Cothon, or inward part of it, is safe in all accidents of weather, and opens into a large navigable pond, formed by the Majerdah or ancient *Bograda*, which at present discharges itself through it, in its way to the sea. The town belonging to this port was formerly very considerable.

RUSCIUD, in *Geography*, a river of Persia, which runs into the Persian gulf, 48 miles W. of Ormus.

RUSCUNIÆ COLONIA, *Temendſiſe*, in *Ancient Geography*, a promontory and colony of the eastern part of Mauritania Cæsariensis, according to Ptolemy, Pliny, Mela, and the Itinerary of Antonine. Antonine places it 15 miles E. of Icoſium. The ruins are still visible.

RUSCURIUM, *Rusuccoræ* of Ptolemy, and the *Rufuccuro* of the Peutingerian Tables, now *Dellys*, formerly an ancient city, but at present a small town, of Africa, on the coast of Algiers, situated partly at the foot and partly upon the declivity of a high mountain. In a wall, just over the harbour, is a small niche, with an image, in the attitude of a Madonna; but the features and drapery, says Dr. Shaw, are defaced.

RUSCUS, in *Botany*, an ancient name, whose derivation has been given up by most authors, as hopeless. De Theis justly observes, that it was originally *Brufcus*, and

this leads him to the Celtic name of the plant in question, *Beufkelen*, equivalent to Box-holly, which is certainly the best explanation that has ever fallen in our way.—Linn. Gen. 534. Schreb. 709. Willd. Sp. Pl. v. 4. 874. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 5. 420. Sm. Fl. Brit. 1073. Juff. 42. Lamarck Illustr. t. 835. Gærtn. t. 16.—Class and order, *Dioecia Triandria*. (*D. Syngeneſia*, Linn. *D. Monadelphica*, Willd.) Nat. Ord. *Sarmentaceæ*, Linn. *Aſparagi*, Juff.

Gen. Ch. Male, *Cal.* Perianth of six ovate-oblong, rather spreading, convex leaves, reflexed at the sides. *Cor.* Petals none, except three alternate leaves of the calyx be taken for such. Nectary central, ovate or cylindrical, the size of the calyx, hollow, erect, coloured, perforated at the summit. *Stam.* Filaments none; anthers three, spreading, seated on the extremity of the nectary, connected at the base. *Pist.* obſolete.

Female, *Cal.* as in the male. *Cor.* Petals as in the male. Nectary the same. *Pist.* Germen superior, oblong-ovate, concealed within the nectary; style cylindrical, the length of the nectary; stigma obtuse, projecting out of the orifice. *Peric.* Berry globose, of three cells. *Seeds* two in each cell, globose.

Obſ. There is one species, *R. racemofus*, with united flowers, whose calyx is globose, with six segments at the mouth only. It is seldom met in this genus and its allies, *Smilax*, *Tamus*, *Convallaria*, &c., the feeds all come to maturity. One of them commonly suffocates the rest.

Eff. Ch. Male, Calyx of six leaves. Petals none. Nectary ovate, tubular, bearing the stamens on its margin within.

Female, Calyx and Nectary like the male. Stamens none. Style one. Berry superior, of three cells, feeds originally two in each cell.

The species of this genus are not in general truly shrubby, but biennial evergreens, with perennial roots. Their young shoots resemble asparagus.

The substance of the herbage is peculiarly hard and rigid. The green colour either dark and opaque, or bright and polished. Flowers in most instances borne by the leaves.

1. *R. aculeatus*. Prickly Butcher's-broom. Linn. Sp. Pl. 1474. Willd. n. 1. Ait. n. 1. Fl. Brit. n. 1. Engl. Bot. t. 560. Woodv. Med. Bot. suppl. t. 237. Mill. Illustr. t. 96. (*Rufcus*; Ger. Em. 907. Matth. Valgr. v. 2. 555. Camer. Epit. 935.)

β. *R. laxus*; Sm. Tr. of Linn. Soc. v. 3. 334. (*R. flexuosus*; Mill. Dict. ed. 8. n. 6.)

Leaves sharply pointed, flowering on the upper side, without a leaflet.—Native of bushy woody places, throughout the middle and southern countries of Europe, especially on a gravelly or barren soil, flowering early in spring. Not uncommon in England. The variety β was observed at Stoke, near Gosport, by Mr. G. Caley, growing plentifully. This is an old inhabitant of Chelsea garden, and we have no hesitation in adopting professor Martyn's opinion, as to Miller's synonym. The root of this species is branched, and rather creeping. *Plant* truly herbaceous, though so firm and rigid. After living one year without flowering, and remaining in leaf all the winter, it dies down to the root, after ripening fruit, in the following autumn. Every part is devoid of pubescence. *Stems* about two feet high, round, striated, branched, rather spreading. *Leaves* alternate, spreading every way, not quite sessile, twisted, hard, ovate, entire, tipped with a sharp thorn, and bearing a solitary pale flower about the middle of their upper side. *Nectary* purplish. *Berry* scarlet, the size of

a black currant, with a sweet pulp, enclosing one or two large, shining, globular, horny or semitransparent seeds. The above-mentioned variety has longer, more lax, branches, and elliptical leaves, tapering at each end; but there are many intermediate states, which connect it with the common kind. Mr. Woodward has rightly observed, that the flower has a real stalk, immersed in the leaf, under the cuticle. We would remark, that the strict union of the leaves and the branches, in this genus, is like that of Mosses, and Ferns, which last they resemble further in mode of inflorescence, and exceed them in firmness of texture.

2. *R. Hypophyllum*. Broad-leaved Butcher's-broom. Linn. Sp. Pl. 1474. Willd. n. 2. Ait. n. 2. (*Laurus alexandrina* et *Chamædaphne*; Column. Ecphr. 164. t. 165. f. 1.)

β. *R. latifolius*, fructu in medio foliorum extra pendente; Till. Pf. 149. Dill. Elth. 333. t. 251. f. 323.

Leaves flowering on the under side, without a leaflet. —Native of rather hilly situations in Italy. Dr. Sibthorp gathered it also on mount Athos, in shady woods, and took it for the *Χαμαδάφνη* of Dioscorides, of which we conceive there can be no doubt. The roots are much like those of the foregoing, but the plant is not branched, and the leaves are much larger, more elliptical, with an acute, but not spinous, point. Each leaf bears, from the middle of its under side, a pair of stalked pendulous flowers, whose segments and nectary are of a more slender form than in the *aculeatus*. Their stalks are accompanied at the base by a small scaly bractea, but not by any accessory leaf, as in the following. The berries are red.

3. *R. Hypoglossum*. Double-leaved Butcher's-broom. Linn. Sp. Pl. 1474. Willd. n. 3. Ait. n. 3. Sm. Fl. Græc. Sibth. t. 955, unpublished. (*Hippoglossum* Dioscoridis, et *Lauro-Taxa* Plinii; Column. Ecphr. 166. *Hypoglossum*; *ibid.* t. 165. *Δάφνη αλεξάνδρεια*, Diosc. Sibth.) —Leaves flowering on the upper side, under a leaflet. —Native of Hungary, Italy, mount Athos, and the borders of the Black sea, in bushy, rather hilly situations. Gerarde appears to have cultivated it in 1596. The plant is kept in some curious gardens, where it blossoms imperfectly early in spring, but we have never seen the berries, which in Dr. Sibthorp's figure make a beautiful appearance, being of a deep rich scarlet, the size of black currants. The habit of this species is like the last, but the leaves, though variable in breadth, are commonly narrower, and particularly distinguished by the small leaf on their disk, from beneath which proceeds a solitary, stalked, pale-green flower, with a slender, purplish, curved, furrowed nectary. The stems are simple, scarcely a foot high, not quite erect.

4. *R. androgynus*. Climbing Butcher's-broom. Linn. Sp. Pl. 1474. Willd. n. 4. Ait. n. 4. (*R. latifolius*, è foliorum sinu florifer et baccifer; Dill. Elth. 332. t. 250.) —Stem twining, branched. Leaves flowering at the edge. —Native of the Canary islands, and long cultivated in England, where it proves a hardy green-house plant, flowering most part of the summer. We have never seen this species in such perfection as in the celebrated garden of the late Dr. Fothergill at Upton, where, under the fostering care of his worthy successors, several relics of his collection still remain. The *Ruscus*, trained up the inside of the old green-house, to the height of many feet, makes a very elegant appearance with its broad, ovate, drooping leaves, of a rich shining green, from one of whose margins proceeds a copious tuft of cream-coloured flowers, male and female on the same plant. The berries are described by Dillenius nearly the size of the last, yellowish, and usually solitary, one ripe seed in each.

5. *R. racemosus*. Alexandrian Laurel, or Clustered Butcher's-broom. Linn. Sp. Pl. 1474. Willd. n. 5. (*Laurus alexandrina angustifolia ramola*; Morif. sect. 13. t. 5. f. 4. *L. alexandrina*, fructu è summitate caulium prodeunte; Herm. Lugd. Bat. 679. t. 681.) —Stem erect, branched. Cluster terminal. Flowers united. —Native of Portugal, according to Mr. Aiton. Linnæus was unacquainted with its origin, and Willdenow by mistake, it seems, mentions the islands of the Archipelago, as Dr. Sibthorp did not observe the plant any where in his tour, though he could not possibly have over-looked it at any season of the year. Nothing is more common in shrubberies, and rustic gardens. The stems are bushy, from two to four feet high. Leaves sessile, lanceolate, twisted, of a bright and polished green. Flowers in terminal clusters, pale buff or cream-coloured, the stamens and pistils complete in each flower, but they afford no great quantity of fruit; except occasionally, in retired country situations, where the herb grows luxuriantly. The berries are orange-coloured.

6. *R. reticulatus*. Reticulated Butcher's-broom. Thunb. Prodr. 13. Willd. n. 6. —“Stem climbing. Leaves ovate, many-ribbed, reticulated. Flowers solitary, stalked.” —Native of the Cape of Good Hope.

7. *R. volubilis*. Twining Butcher's-broom. Thunb. Prodr. 13. Willd. n. 7. —“Stem twining. Leaves ovate-oblong, many-ribbed.” —From the same country. We know nothing of this or the last, but from Thunberg's short definitions.

—Miller has a *R. trifolius*, from Zante and the Greek islands, which professor Martyn justly prefers to *Hypophyllum*. The same author describes another species, under the name of *R. frutescens*, gathered by Houttoun near Carthage. This we conceive to be a *Jacquinia*; probably the *ruscifolia* of Linnæus.

*Ruscus*, in Gardening, contains plants of the shrubby and under-shrubby evergreen kind, of which the species cultivated are, the prickly-butcher's-broom (*R. aculeatus*); the broad-leaved butcher's-broom (*R. hypophyllum*); the double-leaved butcher's-broom (*R. hypoglossum*); the Alexandrian laurel (*R. racemosus*); and the climbing butcher's-broom (*R. androgynus*).

*Method of Culture*.—These plants are capable of being readily increased by the roots, which send up numerous stalks or suckers, which may be taken up in autumn, winter, or spring in open weather, and divided into many separate sets, each forming a proper plant, though they need not be divided very small unless where a great increase is required, planting the largest at once where they are to remain, and the smallest in nursery rows, &c., when each plant soon increases by offsets, and assumes a bushy growth. They are also capable of being raised from seeds, but they often remain in the ground till the second spring. The seeds of the hardy sort should be sown in any bed or border an inch deep, and the tender kind in pots, placed under shelter in cold weather; and when the plants are a year old, pricking them out in March, the hardy sorts in nursery-beds for two or three years, and the tender sorts in pots.

All the different hardy sorts are proper for being placed out near the verges of shrubberies, or any close plantations, as they thrive under the drip of trees, and remain green the year round. But the last tender sort requires the shelter of a green-house in winter, where it affords variety among other potted plants of that kind.

RUSE, in Geography, a town of European Turkey, in Romania; 60 miles N.E. of Adrianople.

RUSECK, a town of Bohemia, in the circle of Konigin-gratz; two miles N. of Konigingratz.

RUSEI, a town of Walachia, in the Kodmana; 45 miles W. of Bucharest. N. lat.  $44^{\circ} 21'$ . E. long.  $24^{\circ} 47'$ .

RUSGONIA, in *Ancient Geography*, *Ruslionum* of Ptolemy, *Ruthifia* of Mela, and *Rufonia* of Pliny and others, a cape near Algiers, on the coast of Africa, now Temenduse, or Metalus, with a tabled land, as the mariners call a flat hillock that rises up in the middle of it. The Turks have here a small castle for the security of the adjacent roads, once the chief station of their navy, where are still the traces of an ancient Cothon, with several heaps of ruins of the same extent with those of Tefessad, and which have no less contributed to the fortification of Algiers.

RUSH, BENJAMIN, in *Biography*, an eminent physician, and professor of the institutes and practice of medicine in the university of Pennsylvania, was born near Bristol, in the state of Pennsylvania, on the 5th of January, 1745. His ancestors belonged to the society of Quakers, and were of the number of those who followed the celebrated William Penn to Pennsylvania, in the year 1683: his grandfather, James Rush, resided on his estate near Philadelphia, and died in the year 1727: his son, who was the father of the subject of these memoirs, inherited both his farm and his trade, which was that of a gun-smith. He died while Benjamin was yet young. His widow, a most excellent woman, upon whom the education of young Rush thus necessarily devolved, placed him, at an early age, under the direction of the late Rev. Samuel Finley, at West Nottingham, in Chester county, Pennsylvania, by whom he was taught the rudiments of classical knowledge. Dr. Finley, afterwards better known as the president of Princeton college, New Jersey, was an able scholar and faithful teacher, and, being also related to Mrs. Rush, may be supposed to have paid great attention to the improvement of his young pupil. But whatever may have been the assiduity with which his education was directed by his preceptor, he possessed an ardent desire for knowledge, and was most unwearied in the pursuit of it.

From the academy of Dr. Finley he was removed to the college of Princeton, where he finished his classical education, and was admitted to the degree of A. B. in 1760, when he had not yet completed his sixteenth year. He was now left to choose a profession, and in the choice which he made, he doubtless was actuated by conscientious motives. He seems to have fully known his own character, and to have formed a proper estimate of his talents, and by applying them to the science and practice of medicine, to have been desirous of doing all possible good to the family of mankind. That he was directed by these motives, may be inferred from his own opinion of the utility of medicine. "So great," says he, "are the blessings which mankind derive from it, that if every other argument failed to prove the administration of a providence in human affairs, the profession of medicine would be fully sufficient for that purpose."

He accordingly, soon after leaving college, placed himself under the care of the late Dr. John Redman, of Philadelphia, a gentleman who had deservedly obtained an extensive share of professional business, and who was justly considered an excellent practitioner. With Dr. Redman young Rush continued some time, zealously engaged in the acquisition of the several branches of medicine. At that day, however, no institution for the purpose of medical instruction was established in Philadelphia, and his thirst for knowledge being rather excited than gratified with what he had learned from his preceptor, he formed the resolution of

going abroad in order to avail himself of those advantages which were not within his reach in his native country. The university of Edinburgh, at that time, was at the zenith of its reputation, and justly boasted of its able professors, among whom were the elder Munro, the elder Gregory, Dr. Cullen, and Dr. Black. Thither Rush repaired, and was graduated M.D. in 1768, after having performed the usual collegiate duties with much honour, and published his inaugural dissertation "De Concoctione Ciborum in Ventriculo." In this performance he candidly acknowledged himself indebted, for many of the opinions which he advanced, to his distinguished teacher Dr. Cullen.

About the period of Dr. Rush's return to his native country, the first attempt was made in Philadelphia for the organization of a medical school. Lectures on anatomy and surgery had indeed been delivered in that city, in 1763 and 1764, to a small class of pupils, by the late Dr. William Shippen, who, two years before, had returned from Europe, where he had completed his education under the direction of the celebrated Dr. William Hunter; and, in 1765, Dr. John Morgan, also, gave instruction on the institutes of medicine and the practice of physic. Three years after this, the venerable Dr. Kuhn, who had been a pupil of the illustrious Linnæus, and had preceded Dr. Rush in his medical honours at Edinburgh only one year, was made the professor of botany and the materia medica. To this list of teachers, Dr. Rush himself was added as professor of chemistry, immediately upon his arrival from England in 1769. Such was the first organization of the medical college of Philadelphia.

That Dr. Rush had, in an eminent degree, the qualifications of a teacher, and discharged with exemplary fidelity the important duties belonging to the elevated station to which he was chosen, the popularity attending his lectures, the yearly increase in the number of his hearers, and the unexampled growth of the college with which he was connected, bear ample testimony. Shortly after this period, he was elected a fellow, and also one of the curators of the American Philosophical Society.

While Dr. Rush was thus engaged in the active pursuits of his profession, the dispute of the then American colonies with Great Britain arose. Considering the claims of the British government unjust, he entered with warmth into the defence of the rights of his countrymen. His talents were already well known, and the fullest confidence was placed in his integrity and patriotism. The crisis demanded his services; and in the year 1776 he was chosen a member of congress for the state of Pennsylvania, and, on the 4th of July, with eight other delegates from that state, he signed the instrument of independence. Upon the 11th day of April, 1777, he was appointed surgeon-general of the military hospital in the middle department. His colleague in the medical school, Dr. Shippen, on the same day was appointed director-general of all the military hospitals for the armies of the United States, and Dr. J. Jones was made physician-general of the hospital in the middle department. The office of surgeon-general was not long held by Dr. Rush, for upon the 1st of July, 1777, he was created physician-general of the hospital, in the middle department, in the room of Dr. Jones.

On the 6th of February ensuing, Dr. Rush resigned the station of physician-general, and Dr. William Brown was appointed in his place.

Doctor Rush, however, still continued to take an active part in the politics of the state to which he belonged. The original government of Pennsylvania is known to have been perfectly unique in its form, and the constant source of in-

calculable mischief. The house of representatives, chosen annually by the people, and on which there was no check, was the sole legislative power; and each succeeding assembly often made it their business to undo all that their predecessors had done. This kind of government was justly-reprobated by Dr. Rush, and the necessity and wisdom of a reformation in it were too apparent not to be attempted. Dr. Rush, and many other distinguished abettors of the cause, had soon after the satisfaction of seeing a new form of government established in Pennsylvania, by a general convention of the people.

Soon after, he formed the resolution of retiring from political life, and of devoting the remainder of his days, with increased ardour, to his profession. He was still further induced to this resolution, from the consideration of the state of medicine in his native country at that time, which, it is scarcely necessary to remark, was in a very low condition. Happy for medical science and the interests of humanity, that he so early formed such a resolution, and that he was so steady, uniform, and indefatigable in the accomplishment of it!

During the long and brilliant career of Dr. Rush's life, from this time to its termination, he may be considered as exclusively occupied in duties pertaining to his profession, and not unlike another Howard, in "surveying the mansions of sorrow and pain," and in mitigating and removing the distresses of all within his power. His biography, therefore, like that of most other scientific men, consists chiefly in a history of his professional labours. How numerous and important his services, as an author, have been, will be readily seen from a brief detail of his writings, which we shall attempt to give, as nearly as practicable, in chronological order.

The first fruits of his professional labours, as an author, was an account of the effects of the Stramonium, or thorn apple; this appeared in the year 1770, and was published in the Transactions of the American Philosophical Society, vol. i. The same year he addressed a letter, on the usefulness of Wort in ill-conditioned ulcers, to his friend Dr. Huck, of London, which was published in the Medical Observations and Inquiries of London, vol. iv. In 1774 he read, before the Philosophical Society, his interesting Inquiry into the Natural History of Medicine among the Indians of North America, which formed the subject of an anniversary oration. He this year again addressed another letter to Dr. Huck, containing some remarks on Bilious fevers, which was printed in the London Medical Observations and Inquiries, vol. v. To this succeeded his Account of the Influence of the Military and Political Events of the American Revolution upon the Human Body, and Observations upon the Diseases of the Military Hospitals of the United States, which his situation in the army eminently qualified him to make. In 1785 he offered to the Philosophical Society of Philadelphia an Inquiry into the Cause of the Increase of Bilious and Intermitting Fevers in Pennsylvania, published in their Transactions, vol. ii.; and soon after, in quick succession, appeared Observations on Tetanus, an Inquiry into the Influence of Physical Causes upon the Moral Faculty, Remarks on the Effects of Ardent Spirits upon the Body and Mind, and his Inquiry into the Causes and Cure of the Pulmonary Consumption. About this time, also, appeared his paper entitled Information to Europeans disposed to migrate to the United States, in a letter to a friend in Great Britain; a subject which had already occupied the attention of Dr. Franklin, but which Dr. Rush considered still further deserving notice, on account of the important changes which the United States had

lately undergone. To this paper followed his Observations on the Population of Pennsylvania, Observations on Tobacco, and his Essay on the Study of the Latin and Greek Languages, which was first published in the American Museum of Philadelphia. This last mentioned paper, which has been the fertile topic of much animadversion, was, with several other essays of Dr. Rush, and his Eulogiums on Dr. Cullen and the illustrious Rittenhouse, the former delivered in 1790, the latter in 1796, embodied in an octavo volume, entitled Essays, Literary, Moral, and Philosophical, and published in 1798.

In 1791, the medical colleges of Philadelphia, which, on account of certain legislative proceedings, had existed as two distinct establishments since the year 1788, became united under the name of the University of Pennsylvania; and Dr. Rush was appointed to the chair of the professorship of the institutes of medicine and clinical practice. He now gave to the public his Lectures upon the Cause of Animal Life. The same year he presented the Philosophical Society his Account of the Sugar Maple Tree of the United States, which was published in their Transactions, vol. iii.; and in 1792, Observations, intended to favour a supposition that the Black Colour of the Negro is derived from Leprosy; published in their Transactions, vol. iv.

The year 1793 is memorable in the medical annals of the United States, on account of the great mortality occasioned by the yellow fever, which prevailed in the city of Philadelphia; and the history of that epidemic, which was published by Dr. Rush in 1794, cannot be too highly valued, both for his minute and accurate description of the disease, and the many important facts he has recorded in relation to it. It was comprised in one volume octavo, and has undergone several editions, and been extensively circulated in the Spanish and in the French languages. About this period, also, he offered to the medical world his observations on the Symptoms and Cure of Dropsy in general, and on Hydrocephalus Internus; an Account of the Influenza, as it appeared in Philadelphia in 1789, 1790, and 1791; and Observations on the State of the Body and Mind in Old Age. In 1797 came out his Observations on the Nature and Cure of Gout, and on Hydrophobia; an Inquiry into the Cause and Cure of the Cholera Infantum; Observations on Cynanche Trachealis, &c.

It is proper to state, as connected with the literary labours of Dr. Rush, that in 1788, many of his medical papers were collected together, and that he offered them to the public under the title of Medical Inquiries and Observations, vol. i. These he, from time to time, continued, embracing most of the writings above enumerated, besides observations on the climate of Pennsylvania, and some others, until a fifth volume was completed in 1798. In 1801 he added to his character as a writer, by the publication of six Introductory Lectures to a course of Lectures upon the Institutes and Practice of Medicine, delivered in the University of Pennsylvania. In 1804 a new and corrected edition of his Medical Inquiries, &c. was printed in four volumes, octavo. In 1806 he also published a second edition of his Essays. In 1809, such was the demand for the Medical Inquiries and Observations, he again revised and enlarged the work throughout, and enriched the medical profession with a third edition. In this edition he continued his several histories of the yellow fever, as it prevailed in Philadelphia from 1793 to 1809. It also contained a Defence of Blood-letting, as a Remedy for certain Diseases; a view of the comparative state of Medicine in Philadelphia between the years 1760 and 1766, and the year 1809; an Inquiry into the various sources of the usual forms of Sum-

mer and Autumnal Diseases in the United States, and the means of preventing them; and the recantation of his opinion of the Contagious nature of the Yellow Fever.

He now formed the idea of selecting some of the best practical works for republication in America, and in order to render them more useful, of adding to them such notes as might be better adapted to the diseases of his own country. His editions of Sydenham and of Cleghorn were published in 1809, and in 1810 appeared those of Pringle and Hillary. In 1811 appeared a volume of Introductory Lectures, containing those he had formerly published, with ten others delivered at different years before his class, and also two upon the pleasures of the senses and of the mind. His work upon the Diseases of the Mind, which had long and ardently been looked for, was next added to his writings. It appeared towards the close of 1812, in one volume octavo. The last effort of his pen was a letter on Hydrophobia, containing additional reasons in support of the theory he had formerly advanced, as to the seat of the disease being chiefly in the blood-vessels. It was addressed to Dr. Holack, and written not many days before his fatal illness.

While thus assiduously engaged in enriching medical science with the valuable fruits of his long and extensive experience, and in the active discharge of the practical duties of his profession, he was, on the evening of the 13th of April, seized with symptoms of general febrile irritation, which were soon accompanied with considerable pain in his chest. His constitution was naturally delicate, and he had acquired, from previous illness, a predisposition to an affection of his lungs. He lost a moderate quantity of blood, by which he felt himself considerably relieved. But his strength was not sufficient to overcome the severity of his complaint; the beneficial effects resulting from the most skilful treatment were but of temporary duration. His disease rapidly assumed a typhus character, attended with great stupor, and a disinclination to conversation. In other respects, however, he retained his faculties, and the perfect consciousness of his approaching dissolution. On Monday evening ensuing, after a short illness of five days, and in the 69th year of his age, he ended his truly valuable and exemplary life. His death was the subject of universal lamentation, and he was followed to the grave by thousands, who assembled to bear testimony to his excellence.

In January, 1776, he married Miss Julia Stockton, daughter of the Hon. Judge Stockton, of New Jersey, a lady of an excellent understanding, and whose amiable disposition and cultivated mind eminently qualified her as the companion of Dr. Rush. Thirteen children were the fruits of their marriage, nine of whom still survive. Two of these are chosen to offices of high respectability in the general government of the United States.

It were no easy task to do adequate justice to the great talents, the useful labours, and the exemplary character of Dr. Rush. From the preceding sketch, it is presumed, some idea may be formed of his incessant devotedness to the improvement of that profession of which he was so bright an ornament. His merits, as a practitioner, are too well known to need particular notice; he was fully aware of the great responsibility attached to the medical character, and uniformly evinced the deepest solicitude for the recovery of his patient. His kindness and liberality in imparting aid to those from whom no remuneration was ever to be expected were unbounded, and arose from the generous impulse of his nature, the cordial concern he felt in whatever affected the interests of his fellow creatures. His mind was of a superior order: to a perception naturally ready and acute, he

united a discriminating judgment, a retentive memory, which was greatly improved by habits of close attention, a brilliant imagination, and a highly cultivated taste. He possessed a comprehensive understanding; his knowledge was varied and profound, and he eminently excelled in the several departments of his profession. In his assiduity and perseverance in the acquisition of knowledge he had no superior, and few equals. Accustomed to constant and regular exercise, his intellectual powers acquired additional vigour from employment. Notwithstanding the great fatigue he had to undergo in the discharge of the practical duties of a laborious profession, and the constant interruptions to which he was exposed, when engaged in his pursuits as an author, he never for a moment abated of his ardour in the cause of science. His habits of punctuality to every kind of business in which he was employed, added to a judicious arrangement of time for his multifarious occupations, secured to him sufficient leisure for the publication of those works which have given such celebrity to his name.

His writings claim our attention, both on account of their extent and their variety. Instead of being a mere collator of the opinions of others, he was constantly making discoveries and improvements of his own, and from the results of his individual experience and observation, added more facts to the science of medicine, than all who had preceded him in his native country. His description of diseases, for minuteness and accuracy of detail, cannot be exceeded, and may safely be regarded as models of their kind. His volume on the diseases of the mind, as far as it exhibits the infinitely varied forms which those diseases exhibit, is a storehouse of instruction. Had his labours been limited to these subjects alone, his character would deservedly have been cherished by future ages. His reputation, however, will permanently depend upon his several histories of the epidemics of the United States, which have rendered his name familiar wherever medical science is cultivated, and will hereafter cause to be inscribed upon the same imperishable column that bears testimony to the merits of Sydenham and Boerhaave, the illustrious name of Benjamin Rush. The respect and consideration which his publications procured for him among his contemporaries, were such, that the highest honours were accumulated upon him in different parts of Europe, as well as in his own country, and he was admitted a member of many of the most distinguished literary and philosophical associations.

There are other qualities which still more entitled Dr. Rush to our respect and esteem. In private life, his disposition and deportment were in the highest degree exemplary. Admired and courted for his intellectual endowments, he riveted to him the affections of all who enjoyed the pleasure of an intimate acquaintance. The affability of his manners, the amiableness of his temper, and the benevolence of his character, were ever conspicuous. He was ardent in his friendships and forgiving in his resentments, and yet entertaining a due regard for himself and a high sense of honour, he possessed a manly independence of spirit which disdained every thing mean and servile. He had an extraordinary command of language, and always imparted his thoughts in a peculiarly impressive and eloquent manner. Those who had the happiness to experience the delights of his conversation, will long recollect, with pleasure, his unassuming modesty, and the rich stores of knowledge he poured forth on the most instructive topics. Even when his opinions were solicited, they were given, not as the dictates or admonitions of a superior, but as the kind advice of a friend and equal. He never evinced any of that haughtiness and affectation of importance, which sometimes attaches to

men of eminence, and which so materially lessens the pleasures and comforts of social life.

He was a believer in Christianity from an examination of its principles and the deepest conviction. The purity of its doctrines, and the excellence of its precepts, were a frequent topic of his conversation; its practical influence upon his conduct through life he often acknowledged, and cherished with a fervent hope the animating prospects it affords. His writings, in numerous places, bear testimony to his Christian virtues; and in a manuscript letter, written a short time previous to his fatal illness, and now before the writer of this imperfect sketch, he candidly declares that he had "acquired and received nothing from the world which he so highly prized as the religious principles he received from his parents." It is peculiarly gratifying to observe a man so distinguished in a profession in which, by the illiberal, religious scepticism is supposed to abound, directing his talents to the maintenance of genuine piety, and the enforcing of Christian virtue. To inculcate those principles which flow from the source of all truth and purity, and to impart them as a legacy to his children, was an object dear to his heart, and which he never failed to promote by constant exhortation and the powerful influence of his own example.

There is one particular circumstance in the character of Dr. Rush, which we cannot permit to be passed over without observation; we allude to the union, so eminently conspicuous in him, of the eminent practitioner, and the able and voluminous writer. But our limits will not allow us to enlarge. The materials of the above biographical article have been extracted from the American Medical and Philosophical Register, conducted by Dr. Hosack and Dr. Francis, of New York; July, 1813.

RUSH, in *Botany*. See JUNCUS.

Rushes always indicate a deepish rich soil, and they thrive most in land that is too wet and cold for most other plants. It has been observed that plants of the rush kind may be easily removed by preventing the stagnation of moisture near the surface by judicious under or surface draining, and the application of substances of the saline or calcareous kinds, as ashes, lime, drift from the roads, and other similar materials. These are best made use of in a dry season in either the autumn or spring, but the latter is probably the best; as these absorbent materials will thereby be made use of at the time such plants begin to shoot and establish themselves, and when there will be the least danger of their operation being lessened or prevented by too great a degree of moisture. It has been stated by Mr. Kent, that in naturally coarse meadows, or such as become so in consequence of rushes growing upon them before they have been rendered sufficiently dry by draining, it forms a great improvement to apply a thin coat of sand evenly over the surface of them in the proportion of from twenty to thirty common loads. By this means the sward is rendered much finer, and a much better sort of herbage brought up, white clover being predominant in most cases. And there is still another method, that, in particular situations, may be more easy and convenient, and which has been found to quickly destroy plants of this coarse kind by bringing up those of a finer description. It is a mode that may, at first, seem singular to those who have not seen its sudden and astonishing effects. It is that of conducting water over the surface of such ground; but in this intention it should not be suffered to have the least degree of stagnation, but be conveyed off with as much expedition as possible, by suitable drains being made. Frequent cutting over while in their young growth has also been found useful in destroying them.

Another method of destroying rushes is to fork them up

clean by the roots in July, and after having let them lie a fortnight or three weeks to dry, lay them in heaps and burn them gently, and the ashes which these afford will be tolerable manure for the land; but, in order to prevent their growing again, and to make the pasture good, the land should be drained, otherwise there will be no destroying them entirely; but after it is well drained, if the roots are annually drawn up, and the ground kept duly rolled, they may be subdued. Miller.

RUSH, *Flowering*, or *Water Gladiol*. See BUTOMUS.

RUSH, *Lesser Flowering*. See SCHEUCHZERIA.

RUSH, *Round, Black-headed, Marsh*, or *Bog*. See SCHOE-  
NUS.

RUSH, *Sweet*. See ACORUS.

RUSH-*Grass*. See SCIRPUS.

RUSHES, *Petrified*. What is usually called by this name is a kind of fossil coral. But we have in England, also, another not uncommon substance, frequently called by the same name: this is an incrustation of sparry matter, in the form of a stony crust on the outsidings of real rushes; though, in this case, it is no real petrification, but only a covering of this stone-like matter.

Incrustations and petrifications are usually confounded together, and the generality of people do not attend to the distinction, which is, that in a real petrification, the stony matter penetrates the very substance of the body, as is the case in the petrified wood of Ireland, and other places; whereas, in these incrustations the substance itself remains unaltered within, and its outer part alone is covered with the stony substance; this is the case with what is called the petrified moss at Scarborough, and in other parts of England, and this is the case in regard to what we call sometimes petrified rushes.

RUSH, in *Rural Economy*, a term signifying a tuft, cluster, or a knot of plants of the corn or grass kind.

RUSHES is also a term provincially applied to the wire rush.

RUSH, in *Geography*, a fishing-town of the county of Dublin, Ireland, well situated for carrying on business to advantage. The ling cured here, of which much is exported, is celebrated for its superior flavour. It is situated on a point of land projecting into the Irish sea; 13½ miles N. by E. from Dublin.

RUSH, *The*, a sand-bank near the E. coast of Ireland, and county of Wexford, about four miles long, and hardly one broad; a little to the south of Glasfarrick Point.

RUSHA, a small island near the W. coast of Scotland. N. lat. 58°. W. long. 2° 20'.

RUSHIN, or CASTLE RUSHIN. See CASTLE-TOWN.

RUSHWORTH, JOHN, in *Biography*, was born in or about the year 1607, somewhere in the county of Northumberland. Of the early part of his education we have no account. He was some time a student in the university of Oxford, after which he entered himself at Lincoln's Inn, and was called to the bar. He was, however, more attached to politics than to the pursuits of the profession, and was almost perpetually an attendant on the parliament, star-chamber, and other courts, taking notes, in short-hand, of the proceedings at those places. In the troubles of that period he attached himself to the parliamentary and presbyterian parties, and in 1640 he was admitted an assistant clerk of the house of commons. He soon gained the confidence of the house, and, during the king's residence at York, was employed to convey to him its addresses and messages, on which occasions he is said, even at that period, to have rode from London to that city in 24 hours. For these services he was recommended by the house

o a place in the excise. In 1643 he took the covenant, and sir Thomas Fairfax, to whom he was nearly related, being made general of the parliamentary forces, appointed Mr. Rushworth to be his secretary. In this situation he was very zealous and active in performing his duties, public and private. In 1649 he attended Fairfax to Oxford, where he was created M.A. as a member of Queen's college. When Fairfax resigned his commission, Rushworth took up his residence in London, and was nominated in 1652, by the house of commons, one of the commissioners to reform abuses in the common law. At this time he was engaged in the compilation of his "Historical Collections," of which the first part appeared in 1659, dedicated to Richard Cromwell, at that time Protector. He was at this period member of parliament for Berwick-upon-Tweed. In 1660 he was appointed one of the clerks of the new council of state. After the Restoration, he endeavoured to ingratiate himself with Charles II. by presenting to him several books of the privy-council during the former reign, which he had preserved from destruction, for which, however, he probably received no higher reward than that of thanks. In 1667, sir Orlando Bridgeman, keeper of the great seal, made him his secretary, when he was again elected representative for Berwick in the parliament of 1678-9, and the subsequent one held at Oxford. After the dissolution of the latter, having always been careless of his private affairs, he fell into necessitous circumstances, and lived in great obscurity in Westminster, assiduously employed in his Collections, of which he published the second part in 1680. He was at length arrested for debt, and committed to the king's bench prison, where he spent, in great wretchedness, the last six years of his life. He died in 1690, at the age of 83. He had several daughters, one of whom was married to sir Francis Vane. The "Historical Collections" of this author include private passages of state, weighty matters of law, remarkable proceedings in parliament, &c. and they commence in the reign of king James, in the year 1618, and were brought down to 1740. The third and fourth parts, printed from his MSS., extend to the death of Charles I. in 1648-9. The whole was reprinted uniformly in 7 volumes, folio, in 1721. Of his Collections, the writer in the Biographia Britannica says, all that have written on the Puritan or Presbyterian side have highly extolled, nay almost idolized them; such as Coke, Rapin, Oldmixon, &c. Others, on the contrary, who were favourers of king Charles I. and his cause, condemn them as extremely partial, and have discredited them as much as possible. But the person who professedly set himself to oppose them was John Nalson, L.L.D., who published, by command of king Charles II., "An Impartial Collection of the great Affairs of the State, from the Beginning of the Scotch Rebellion in the Year 1639, to the Murder of King Charles I." &c. Dr. Nalson did not continue his history lower than January 1641-2. He brings four capital accusations against Rushworth, viz. that he does not inform us whence he had his materials, and therefore that his facts do not stand upon sufficient authority;—that he prints false and erroneous copies of some papers;—that, under the colour of epitomizing others, he has not only obscured, but, in many places, corrupted and disguised the sense;—and that he has recorded little but what relates to the justification of those whom he favours, and their proceedings, omitting what might serve to manifest the king's innocence. In a compilation of such extent, it is no wonder there should be errors, and the writers of the "Parliamentary History" have taken pains to frame a long list of his mistakes, which is copied in a note to the article RUSHWORTH, in the Biog. Brit.; they, however, attribute them rather to the negligence

and ignorance of transcribers, than to wilful misrepresentation. It can, however, scarcely be expected that a man, writing as he did, should be free from partialities, or that his personal attachments should not enter into his work. Besides, it is certain that the first part of his work was submitted to the revision of Oliver Cromwell, who being too much occupied to examine it himself, put it into the hands of Whitelock, under whom it underwent various alterations. Nevertheless, Mr. Rushworth professes great impartiality and faithfulness, assuming that he must be in possession of a sufficient degree of knowledge and information for all the objects he had in view; and he, moreover, gives himself as an instance, that it is possible for a man to be of a *party* and not *partial*. The value of the "Historical Collections" arises from their having preserved together several detached pieces, which otherwise would have been lost, and from being the fullest compilation during the period of which they treat. Biog. Brit.

RUSHY LAND, in *Agriculture*, that which is much infested and troubled with the growth of rushes upon it. Lands of this nature and quality prevail in many places to very considerable extents, which, when properly reclaimed and managed, constitute extremely good meadows and pastures. They are also, in some cases, capable of being broken up and converted to the purpose of tillage, with great advantage.

In many instances of this nature, very great benefit has been derived from a thick covering of chalk rubbish, or the rubbish of lime-stone and free-stone quarries, applied in a considerably reduced or powdery state, after the land had been sufficiently freed from stagnant water by means of pipe or other kinds of under draining, as such heavy materials soon sink in the ground, and by consolidating it are the cause of bringing up another sort of better plants of the grass kind. When such rushy lands have once acquired a certain state and degree of firmness by these or any other means, they may be further benefited and improved by rolling, and close feeding down with sheep stock, which should be confined on particular portions of them, in great numbers, in order to insure the fullest effect and advantage.

It is better likewise, where they are capable of it, to let these sorts of lands remain for some years in the state of pasture, than to bring them directly under the mowing system; as, in that way, they are constantly advancing to a more solid and finer state of herbage, whereas under the contrary practice, they are invariably getting more open, loose, and coarse in their produce. See RUSH.

RUSIBIS PORTUS, in *Ancient Geography*, a port of Africa, in Mauritania Tingitana, between the mouth of the river Cofa and that of Afama, according to Ptolemy. It is called *Rubis Portus* by Pliny.

RUSICADA, SGIGATA, a town of Africa, according to Mela and Ptolemy. It was situated towards the middle of the gulf of Numidia, about 30 miles E. of Collops Magnus. In the Itinerary of Antonine, this town is placed in Mauritania Cæsariensis, upon the route from Carthage to Leninx, between Chuli Municipium and Paratianæ. Here are some remains of antiquity. Its cisterns serve as a corn magazine.

RUSICIBAR, a town of Africa, in Mauritania Cæsariensis, between Rustonium and Modinga, according to Ptolemy. Antonine calls it Rufubbari, and in the Penteingean Tables it is Rufibricari Matidæ.

RUSIN, in *Geography*, a town of Bohemia, in the circle of Schlan; 4 miles N. W. of Prague.

RUSK, AL, a town of Curdillan; 18 miles S. E. of Amadich.

RUSKO, a town of Sweden, in the government of Abo ; 6 miles N.W. of Abo.

RUSKOBAGAN, the Indian name of Parker's island in Kennebeck river.

RUSKY, or RUSKYBRIDGE, a small post-town of Ireland, in the county of Leitrim, where there is a bridge over the Shannon. It is 67 miles N. by W. from Dublin, and 7 from Longford.

RUSLAM RIVER, a river of Upper Canada, which runs into lake St. Clair, between Point aux Roches and Belle river ; it is navigable by a loaded boat six miles upwards. The land on its banks is very good, and at the distance of a few miles in ascending it there is an Indian settlement.

RUSMA, in *Natural History*, the name given by the Eastern nations to the substance called by the ancient Greeks *sory*, and used as a depilatory.

The Turks call this substance *rusma*, and the Arabians *nouret*. It is not, as some have imagined, a mineral substance found ready for use, as a depilatory, in the bowels of the earth ; but it requires a preparation and an alloy to give it that property. Bellon, who first described (at Cuta, in Galatia,) "the source of a mineral which they call *rusma*," adds, that this mineral alone cannot be used "till it has been beaten into a very fine powder, putting half as much quick-lime as *rusma*, which is then diluted in a vessel with water." Thus, the *rusma* of Bellon is not of itself a depilatory ; but it contains some caustic matter, which being mixed with lime, gives it that property. This presumption is confirmed by M. Velmont de Bomare, who, having received from Constantinople some small pieces of mineral *rusma*, perceived, that on throwing it upon hot coals, there immediately exhaled from it a vapour, which gives reason for suspecting that it is a "colchitis" mineralized by sulphur and arsenic. This mixture is the true *rusma* of the Turks, and the *nouret* of the Arabs. There are different names of the same substance, or rather of the same composition. It is, in fact, with arsenic or orpiment, mixed with quick-lime, that the drug for taking off the hair is prepared in the Egyptian baths. The proportion is seven parts of lime to three of orpiment. It is necessary for the person who desires to use it, to keep in a very warm place, such as the hot baths of the East, in which a profuse sweat exudes from all parts of the body. The mixture is diluted with water, and lightly rubbed on the parts from which the hair is to be taken off. After a few moments, it will be seen if the hair be loosened ; it can then be plucked out without pain, and the skin is afterwards washed with hot water. Care must be taken, however, that this liniment does not remain on too long, because it would burn the skin. This does not prevent the hair from growing again, and at the end of some time the operation must be repeated.

Mr. Boyle tells us, he made a fine powder of equal parts of *rusma* and quick-lime, and letting them soak a little time in water, they became a soft paste, which he spread on the part he would free from hair ; and after letting this paste lie on about three minutes, he wiped it off with a wet cloth, and found the hair taken away by the roots without any inconvenience to the part.

RUSOER, in *Geography*. See RISOER.

RUSOOLPOUR, a town of Hindoostan, in Allahabad ; 35 miles N. of Gazypour.

RUSPACH, a town of Austria ; five miles S. of Sonneberg.

RUSPÆ, SHE-AH, in *Ancient Geography*, a town of Africa, on the gulf of Numidia, according to Ptolemy, situated between Achola and Brachiodes Externa ; six miles S. of Achola. Some ruins still remain.

RUSPEN, in *Geography*. See ROSZWEIN.

RUSPINA, SAHALEEL, in *Ancient Geography*, a town of Africa, on the gulf of Numidia, between Leptis Minor and Adrumettium, according to Ptolemy. It was situated on the declivity of an eminence about a mile from the sea, S.E. of Adrumettium. It is known by some ancient remains.

RUSPONO, in *Commerce*, a gold coin of Tuscany, which is a piece of 3 sequins, weighing 8 denari 21 grani, Florence weight, and passing for 40 lire or 60 paoli. In gold and silver weight, the pound contains 12 ounces ; the ounce, 24 denari or 576 grani. This pound weighs 11 oz. 2 deniers 8 grains, French poids de Marc, or 5241 English grains ; so that 100lbs. of this weight answer to 91lbs. English troy weight. The assay and value of the ruspono are as follow : compared, as to fineness, with the English standard of 22 carats, and as to value with the mint price of gold in England, *i. e.* 3*l.* 17*s.* 10½*d.* per oz. standard, *viz.*

	Assay.	Weight.	Contents in pure Gold.	Value in Sterling.
	car. gr.	oz. dwt. gr.	grains.	<i>L. s. d.</i>
Ruspono - -	B. 1 3¾	0 6 17¼	160.8	1 8 5½
Zecchino, or sequin	B. 1 3¾	0 2 5¾	53.6	0 9 5¾
Ruspono of Etruria	B. 1 3¾	0 6 17¼	161.6	1 8 6

The impressions on the ruspono are a lily, with the name and title of the reigning prince, thus : FERDINANDUS III. D. G. A. A. M. D. ETR. that is, *Dei Gratia Archidux Austriae, Magnus Dux Etruriae*, (Ferdinand III. by the grace of God, archduke of Austria, grand duke of Tuscany) ; reverse, a figure representing St. John the Baptist ; legend, S. JOANNES BAPTISTA. Some pieces, coined about the year 1738, bear the head of the reigning prince ; legend, FRANCISCUS III. D. G. LOTH. BAR. ET M. ET. D. REX HIER. (Francis III. by the grace of God, duke of Lorraine and Bar, grand duke of Tuscany, king of Jerusalem) ; reverse, arms of the prince ; legend, IN TE DOMINE SPERAVI, (in thee, O Lord, have I hoped).

The new ruspono of the kingdom of Etruria bears the same impressions as above ; legend in those coined in 1803, LUDOVICUS I. D. G. HISP. INF. REX ETRURIAE, (Louis I. by the grace of God, infant of Spain, king of Etruria) ; and in those struck in 1804, CAROLUS I. D. C. REX ET M. ALOYSIA R. RECTRIX, (Charles I. by the grace of God, king of Etruria, and Maria Louisa queen regent).

The sequin of Tuscany has the same impression as the ruspono.

RUSS, in *Geography*, a town of Prussian Lithuania, and principal place of a district, situated at the mouth of the river Ruffe ; 20 miles N.W. of Tilsit.—Alfo, a small island in the East Indian sea, near the W. coast of Nallau. S. lat. 2° 53'. E. long. 99° 48'.

RUSSE, a river of Prussia, one of the branches of the Memmel, which runs into the Curisch Haff.

RUSSELE'E, a town of Asiatic Turkey, in the province of Diarbekir ; 58 miles S. of Mosul.

RUSSELLIA, in *Botany*, received that name from Jacquin, in honour of Dr. Alexander Russell, for many years physician to the English factory at Aleppo, and author of a "Natural History" of that place, published in 1756 ; which was subsequently re-edited by his brother, the late worthy Dr. Patrick Russell, so well known by his works on the Plague, and on Indian Serpents. (See RUSSELL.) This original *Russelia* was neglected by Linnæus ; but in the *Supplementum*, printed

in 1781, his son gave that appellation to another genus, now established under the name of *VAHLLIA*, as will hereafter be shewn when we come to that article. The younger Linnæus appears to have puzzled himself between the words *Ruffelia* and *Rouffea*; for the latter was what his father had intended; see ROUSSEA. The result of all this confusion is, that Jacquin's *Ruffelia* is now finally restored to its due rank.—Jacq. Amer. 178. Schreb. 419. Willd. Sp. Pl. v. 3. 344. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. Epit. 373. Juss. 118. Lamarck Illustr. t. 539.—Class and order, *Didymia Angiospermia*. Nat. Ord. *Personata*, Linn. *Scrophularia*, Juss.

Gen. Ch. *Cal.* Perianth inferior, of one leaf, in five deep, ovate, concave, acute, taper-pointed, erect, small, permanent segments. *Cor.* of one petal, ringent; tube cylindrical, somewhat compressed, erect, several times longer than the calyx, hairy at the lower side internally; limb two-lipped; the upper lip roundish, flat, cloven, spreading, reflexed at the summit; lower rather the longest, in three deep, oblong, obtuse, flat, widely spreading segments. *Stam.* Filaments four, thread-shaped, erect, rather shorter than the tube, two of them longest; anthers ovate. *Pist.* Germen superior, ovate; style thread-shaped, erect, the length of the shorter stamens; stigma globose, undivided. *Peric.* Capsule roundish, beaked with the permanent base of the style, of two cells and two valves, about as long as the calyx. *Seeds* numerous, minute.

Eff. Ch. Calyx in five deep taper-pointed segments. Upper lip of the corolla emarginate; lower in three deep segments; tube much longer than the calyx, hairy within. Stigma globose. Capsule of two cells, and two valves, with many small seeds.

1. *R. farmentosa*. Trailing *Ruffelia*. Jacq. Amer. 178. t. 113. Willd. n. 1.—Leaves ovate, nearly sessile. Stalks axillary, three-flowered. Gathered by Jacquin in woods and bushy places about the Havannah. The stem is shrubby, with numerous long, weak, square, smooth, leafy branches, supporting themselves against the neighbouring bushes, and pendulous at the ends. Leaves opposite, on very short stalks, ovate, acute, ferrated; rather hairy on the margin and upper surface; smooth at the back. Flowers about an inch long, inodorous, of a fine red, growing two or three together on axillary stalks, not so long as the leaves. The partitions of the capsule, being formed of the inflexed valves, probably separate from the central column as the fruit ripens, and led Jacquin to describe the capsule as of one cell. The same thing is observable in *Verbascum*.

2. *R. rotundifolia*. Round-leaved *Ruffelia*. Cavan. Ic. v. 5. 9. t. 415.—Leaves sessile, heart-shaped, roundish. Clusters many-flowered, axillary and terminal, in pairs. Gathered by Louis Née, near Acapulco, flowering and seeding in February, March, and April. The stem is erect, shrubby, four feet high, with obscurely quadrangular, downy branches. Leaves about two inches in diameter, almost orbicular, though somewhat pointed, reticulated with veins, downy, especially when young, broadly ferrated. Flowers scarlet, smaller than the preceding, in twin clusters, with small bristles under each pair of partial stalks. Central column of the capsule hairy. Seeds minute, black. Cavan.

3. *R. multiflora*. Many-flowered *Ruffelia*. Sims in Curt. Mag. t. 1528.—Leaves ovate, pointed, stalked. Cluster terminal, whorled, compound; the stalks cymose. Found by Mr. Cowan, in the mountainous tract of South America, between Vera Cruz and Mexico. Mr. Lambert raised the plant from seed, and it flowered in his stove at Boyton in the autumn of 1812. The stems and branches are

weak and trailing, as in the first species; but the leaves are larger, and the flowers much more numerous, composing dense whorled clusters at the ends of each branch. Corolla scarlet, about the size of *R. farmentosa*, but the points of the calyx are longer.

RUSSELL, Lord WILLIAM, in *Biography*, a distinguished patriot and martyr to the cause of liberty, was the third son of William, the first duke of Bedford, by a daughter of the earl of Somerset. He was born about the year 1641, and was brought up in those principles of liberty of which his father was an assertor, and which are congenial to the spirit of the English constitution. Being in the fervour of youth at the time of the restoration of Charles II. he joined in the gaieties of the court; till his marriage in 1667, with Rachel, second daughter and co-heiress of the earl of Southampton, reclaimed him from any irregularities into which he had fallen, and from this time he bore a most unblemished character. In four parliaments he represented the county of Bedford, highly esteemed for his patriotism and independent spirit. He was looked up to as one of the heads of the Whig party.

“A political intrigue of this period,” says one of his lordship’s biographers, “has brought an imputation on his memory, from which different methods have been taken to clear it. Charles II., one of the most profligate of public characters, had been exasperated against the court of France, by the withdrawing, on account of the marriage of the duke of York’s daughter to the prince of Orange, that pension which he had hitherto been mean enough to receive, and he appeared desirous of joining the continental confederacy against Lewis XIV. A French war being always popular in England, the parliament voted a large supply of men and money for the purpose. The patriots, however, knowing that Charles was not to be truted, and being at the same time full of alarms respecting popery and arbitrary power, were very unwilling to give him the disposal of an army, which might as probably be employed against the liberties of the country, as against France. In this point, therefore, their wishes coincided with those of Lewis, in raising an opposition to the measures of the English court: and by means of a M. de Rouvigny, who was a relation of lady Russell, they intrigued with Barillon, the French ambassador in England. From that minister’s private dispatches, sir John Dalrymple copied, and published in his ‘Memoirs of Great Britain,’ his negotiations on this head, and also a list of members of parliament whom he had actually bribed.” Lord W. Russell is not charged with being one of the number bribed; he and lord Hollis, it is asserted, positively refused to accept of money. There seems, however, little reason to doubt that he took a part in the intrigue. His intentions, no doubt, were perfectly upright: he was zealously inclined to defend the Protestant interest, which he saw was in imminent danger, and he hoped, by the course which was now taken, the blow might be warded off. To his good intentions, therefore, his biographers must appeal for the justification of a step confessedly of a suspicious nature, and not consistent with correct policy.

In the year 1679, the king found it expedient to ingratiate himself with the Whigs, by the appointment of a new privy council, of which lord Shaftesbury was president, and lord William Russell was a member. They soon found that they did not enjoy the king’s confidence, who engaged in some important measures without their concurrence, among which was the recall of the duke of York; several of them resigned, and lord Russell among the number. His sense of the danger to the Protestant religion from a Catholic successor,

induced him to take a most decisive part in the attempt for the exclusion of the duke of York. He went publicly to Westminster-hall, and at the court of king's bench presented the duke as a recusant: this was in June 1680, and in the following November, he carried up the Exclusion-bill to the house of lords, at the head of 200 members of the house of commons. The lead which he took in this matter, as it was highly displeasing to the court, so it carried a great influence with the public, he being a person of high reputation for integrity, a man of very great fortune, and wholly destitute of private ambition. The king dissolved the parliament, and seemed determined to govern without one. Arbitrary principles were openly avowed by the friends of the king, and the cause of liberty, civil and religious, was brought into the greatest hazard.

This state of affairs inspired desperate councils into some of the Whig leaders, and a conspiracy was formed for an insurrection, conducted by a council, consisting of the duke of Monmouth, lords Russell, Essex, and Howard, Algernon Sydney, and Hampden, who were to act in concert with the duke of Argyle, and the Scotch malcontents. Among these leaders different designs prevailed; but it is admitted, that the subject of this article had no other views than to procure the exclusion of the duke of York from the throne, and a redress of grievances. While these schemes were agitating, a minor plot was laid by some inferior conspirators, which consisted of a plan for assassinating the king on his return from Newmarket, at a farm called the Rye-house, and which has given name to this plot. Although it is known that this conspiracy was entirely apart from the scheme of an insurrection, yet two of the persons engaged in the Rye-house plot had access to some of the leaders in the other plan, and the detection of the one plot, led to the discovery of the other, and orders were instantly issued for the apprehension of those engaged in it. Lord William Russell was in consequence committed to the Tower, and after some of the Rye-house conspirators had been condemned and executed, and the nation was fully impressed with horror of a plot supposed to be connected throughout with a design of assassination, he was brought to trial in July 1683. A jury of zealous royalists was packed for the purpose of convicting the prisoner: in the indictment, the noble lord was charged with the treasonable purpose of killing the king, which was made an inference from his being engaged in a plan of insurrection. "On the whole," says Hume, "having described the nature of the evidence produced on the trial, it was undoubtedly proved, that the insurrection had been deliberated on by the prisoner, and fully resolved; the surprisal of the guards deliberated on, but not fully resolved, and that an assassination had not been once mentioned or imagined by him. So far the matter of fact seems certain: but still, with regard to the law, there remained a difficulty, and that an important one. The English laws of treason, both in the manner of defining that crime, and in the proof required, are the mildest and most indulgent, and consequently the most equitable, that are any where to be found. The two chief species of treason contained in the statute of Edw. III. are the compassing and intending of the king's death, and the actually laying of war against him; and by the law of Mary, the crime must be proved by the concurring testimony of two witnesses, to some overt act, tending to these purposes. But the lawyers, partly desirous of paying court to the sovereign, partly convinced of ill consequences which might attend such narrow limitations, had introduced a greater latitude, both in the proof and definition of the crime. It was not required that the two witnesses

should testify the same precise overt act. It was sufficient that they both testified some overt act of the same treason; and though this evasion may seem a subtilty, it had long prevailed in the courts of judicature, and had at last been solemnly fixed by parliament at the trial of lord Strafford. The lawyers had used the same freedom with the law of Edward III. They had observed, that, by that statute, if a man should enter into a conspiracy for a rebellion, should even fix a correspondence with foreign powers for that purpose, should provide arms and money, yet, if he were detected, and no rebellion ensued, he could not be tried for treason. To prevent this inconvenience, which it had been better to remedy by a new law, they had commonly laid their indictment for intending the death of the king, and produced the intention of rebellion as a proof of that other intention. But though this form of indictment and trial was very frequent, and many persons had been convicted and executed upon it, it was unquestionably irregular, and plainly confounded, by a sophism, two species of treason, which the statute not only had distinguished, but meant accurately to distinguish. What made this refinement more exceptionable was, that a law had passed soon after the Restoration; in which the consulting or the intending of a rebellion was, during Charles's life-time, declared treason, and it was required, that the prosecution should be commenced within six months after the crime was committed. Lord Russell's crime fell within the statute of Charles II., but the facts sworn to by two witnesses, were beyond the six months required by law, and to the other facts there was only a single witness, and he an accomplice. Lord Russell perceived this irregularity, and desired to have the point argued by counsel. The chief justice told him, that could not be granted, unless he previously confessed the facts charged upon him." The artificial confounding of two species of treason, though a practice supported by many precedents, is the chief, but not the only, hardship of which the noble lord had to complain on his trial. His defence was feeble, contenting himself with protesting that he never had entertained any design against the life of the king. The jury, after a very short deliberation, found the prisoner guilty. Such a victim was too desirable to the court, and too agreeable to the vindictive feelings of the duke of York, for him to expect the royal mercy; and though his father, whose only son he now was, offered a large sum, a hundred thousand pounds, to the duchess of Portsmouth, for his life; and his excellent wife, the daughter of a most distinguished royalist, implored forgiveness in the most pathetic manner, his doom was irrevocable, and he obtained the remission only of the most ignominious part of the sentence. After his sentence, he was attended by Tillotson and Burnet, who, though afterwards favourers of the revolution, now urged upon the noble victim an acquiescence in the doctrine of non-resistance. This point, however, he was too firm and honest to concede, though a declaration to that purpose offered the only chance of a pardon. It was not quite creditable to the nobleness of his nature, that he should condescend, even to save his life, to write a petitionary and rather humiliating letter to the duke of York, promising to forbear all future opposition to him, should his life be spared. He also wrote a letter to the king, which was not to be delivered to him till after his death: this, though submissive, was not at all abject. It is almost certain he must have taken these steps in compliance with the solicitations of his friends, rather than from the desire of saving his own life; for he refused the generous offer of lord Cavendish to favour his escape, by changing clothes

clothes with him in prison; and he also declined the duke of Monmouth's proposal of surrendering himself, should lord William Russell think it might contribute to his safety. "It will be no advantage to me," he said, "to have my friends die with me." Conjugal affection was the feeling that clung closest to his heart; and when he had taken his last farewell of his wife, he said, "The bitterness of death is now over." He suffered the sentence of his judges with resignation and composure. Some of his expressions imply much good humour in this last extremity. The day before his execution he was seized with a bleeding at the nose: "I shall not now let blood to divert this distemper," said he to Burnet, who was present; "that will be done tomorrow." A little before the sheriffs conducted him to his carriage, that was to convey him to the scaffold, he wound up his watch, "Now I have done," said he, "with time, and henceforth must think solely of eternity."

The execution was performed July 21st, not on Tower-hill, the common place of execution for men of high rank, but in Lincoln's-Inn-Fields, in order that the citizens might be humbled by the spectacle of their once triumphant leader, carried in his coach through the city; a device which, like most others of the kind, produced an effect contrary to what was intended. The multitude imagined they beheld virtue and liberty sitting by his side. As he was the most popular among his own party, so was he the least obnoxious to the opposite faction; and his melancholy fate united every heart, sensible of humanity, in a tender compassion for him. Without the least change of countenance, he laid his head on the block, and at two strokes it was severed from his body. He was, at the time of his death, only 42 years of age. To his character for probity, sincerity, and private worth, even the enemies to his public principles bear testimony. Of his understanding, bishop Burnet says "that he was slow, and of little discourse, and had a true judgment, when he considered things at his own leisure." At Wooburn Abbey is preserved, in gold letters, the speech of lord Russell to the sheriffs, together with the paper delivered by his lordship to them at the place of execution.

Mr. Calamy, in speaking of lord Russell, says, "that an age would not repair the loss to the nation, and whose name should never be mentioned by Englishmen without singular respect." He passed through and left this world, with as great and general a reputation as any one of the age, and his memory will be had in grateful and everlasting remembrance. Honour and friendship attended lord Russell beyond the grave. Lord Cavendish married his eldest son to one of the daughters of his deceased, his murdered friend; for so the deed was described in the act of 1688-9, for reversing the attainder. The house of commons, at the same time, appointed a committee to examine who were the advisers and promoters of the murder of lord Russell. In May 1694 his father, the earl of Bedford, was created marquis of Tavistock and duke of Bedford; and the reasons for bestowing these honours upon him are in part as follow: "That this was not the least, that he was the father to lord Russell, the ornament of his age, whose great merits it was not enough to transmit by history to posterity, but they (the king and queen) were willing to record them in their royal patent, to remain in the family as a monument consecrated to his consummate virtue, whose name could never be forgotten, so long as men preserved any esteem for sanctity of manners, greatness of mind, and a love to their country, constant even to death. Therefore, to solace his excellent father for so great a loss, to celebrate the memory of so noble a son, and to excite his worthy grandson, the

heir of such mighty hopes, more cheerfully to emulate and follow the example of his illustrious father, they entailed this high dignity upon the earl and his posterity."

RUSSELL, Lady RACHEL, the worthy wife of the subject of the foregoing article, distinguished herself equally by the affectionate zeal with which she served her husband, and by the magnanimity with which she bore her loss, and the reverence she cherished for his memory. Upon his trial, she accompanied him into court; and when he was refused a counsel, and permitted only to employ an amanuensis, she stood forth as that assistant, exciting the sympathy and admiration of all the spectators. After his death, she wrote an affecting letter to the king, asserting that the paper delivered by him to the sheriffs was of his own composition, and not dictated by any other person, as had been suspected. She was the faithful guardian of her husband's fame. A few days after the defeat and death of the duke of Monmouth, with whom lord Russell had an intimate connection, she made use of the opportunity for declaring her conviction that his grace's late attempt was a new project, and not at all depending on any former design, if there was any real one, which, she said, she was satisfied, was no more than her lord admitted, viz. talk; and it is possible that conversation might have proceeded so far as to consider, if a remedy for supposed evils might be sought, how it could be formed. "He had," continues her ladyship, "so just a soul, so firm, so good, that he could not warp from such principles that were so, unless misguided by his understanding, and that his own and not another's: for I dare say, as far as he could discern, he never went into any thing considerable upon the mere submission to any one's particular judgment." Lady Russell also, in the same affectionate regard to her lord's memory, after the revolution, made use of her interest in favour of his chaplain, Mr. Samuel Johnson, and was instrumental in procuring him a pension. As she had promised her lord to take care of her own life, for the sake of his children, she was religiously mindful in keeping her promise, and continued his widow to the end of her life, which did not happen till Michaelmas day 1723, at the age of 87. Biog. Brit. Hume. Letters of Lady Rachel Russell.

RUSSELL, ALEXANDER, a physician, who resided several years in the English factory at Aleppo, was a native of Edinburgh, and at an early period of his life was devoted by his father to the profession of medicine. His education was, of course, obtained in his native university; and on coming to London, he was induced to embark for Turkey, and settled at Aleppo, with the appointment of physician to the English factory there. He applied himself assiduously to the acquisition of the language of the country, and to form an acquaintance with the most experienced practitioners, in order to learn their modes of practice. But he soon obtained a proud pre-eminence above all the physicians there, and was consulted by all nations, ranks, and professions, by Franks, Greeks, Armenians, Jews, and even Turks themselves. The pacha of Aleppo particularly distinguished him by his friendship, and this intimacy enabled Dr. Russell to render the most important services to the factory. The pacha, indeed, did not fail to consult him respecting every act of importance; and many criminals, who were natives, owed their lives to the doctor's interposition. The pacha carried his esteem for Dr. Russell so far, that he sent some valuable presents to his aged father, saying to him, "I am obliged for your friendship and assistance."

In 1755 Dr. Russell published his "Natural History of Aleppo,"

Aleppo," a valuable and interesting work, containing especially some important observations relative to the plague, which have been found useful in Europe, and possibly have tended to check the progress of that dreadful scourge. This work has been translated into different European languages.

On his return to England, in 1759, he fixed his residence in the metropolis, and was elected physician to St. Thomas's hospital, a situation which he held to the time of his death, which occurred in 1770. The Royal Society were obliged to Dr. Russell for several valuable communications, and he presented many important papers to the Medical Society.

RUSSELL, PATRICK, brother of the preceding, and his successor as physician to the English factory at Aleppo. He published a copious "Treatise on the Plague," having had ample opportunities of treating that pestilential disease during the years 1760, 1761, and 1762. In this work, besides a journal of the progress, and a medical history of the plague, Dr. P. Russell has inserted a full discussion of the subjects of quarantine, lazarettoes, and of the police to be adopted in times of pestilence. He likewise published a new edition of his brother's "Natural History of Aleppo," upon a very enlarged scale.

RUSSELL, a mysterious character in London, about the middle of the last century. He was regarded as a parasite among people of fashion; seems to have been in Italy, sung in good taste, and composed some very elegant and pleasing English ballads: such as, "Can Love be controlled by Advice;" "At setting Day and rising Morn;" "Young Daphne, brightest Creature;" "If Truth can fix thy wavering Mind;" "Soft God of Sleep;" "Sweet were once the Joys I tasted;" "To curb our Will," &c.

RUSSELL, in *Geography*, a county of Virginia, bounded N. by Greenbriar, and S. by Lee county; containing 6816 inhabitants.—Also, a township in Hampshire county, Massachusetts; 15 miles W. of Springfield; incorporated in 1792, and containing 422 inhabitants.—Also, a township in the county of Leeds, Upper Canada, lying to the northward of Kitley.

RUSSELLÆ, ROSELLE, in *Ancient Geography*, a town of Italy, in Etruria, S.E. of Populonium and Vetuloni, situated on the right of Umbro, and at a small distance from it. It engaged with some other towns in succouring the Latins against the Romans, according to the report of Dionysius Halicarnassus. Pliny says, it became a Roman colony. Some vestiges of it appear at Roselle.

RUSSELLED, in *Rural Economy*, a term signifying withered or shrivelled, as an apple.

RUSSELSHEIM, in *Geography*, a town of Hesse-Darmstadt, on the Maine; 6 miles E. of Mentz.

RUSSELVILLE, a town in Logan county, in the southern part of Kentucky, in a populous part of the state, about 40 miles from Nashville.

RUSSET, a country word for a dark brown colour.

RUSSEY, LE, in *Geography*, a town of France, in the department of the Doubs, and chief place of a canton, in the district of St. Hippolyte; 9 miles S. of it. The place contains 910, and the canton 5455 inhabitants, on a territory of 240 kilometres, in 22 communes.

RUSSGANGENUM, in *Natural History*, a name given by the people of the East Indies to a yellow and brass-like fossile substance, found in many places there; it resembles the marcasites, only that on trial it is found to contain very little sulphur: it is probably an ore of zinc.

RUSSI, in *Geography*, a town of Italy, in the department of the Amona; 8 miles N.E. of Faenza.

RUSSIA comprehends, in its most general acceptation, the whole Russian empire; but in a more limited sense, it properly includes those principalities and provinces, which for many past ages, *i. e.* for about 1300 or 1400 years, have been inhabited by Russians. In this latter sense its divisions are as follow: *viz.* 1. Great Russia, to which the name of Russia, in the strictest import, has been applied, and which comprises those large tracts of country, under different denominations, that have, without interruptions, composed the Russian dominion, such as Moscow, Vladimir, Novgorod, &c. &c. 2. Little Russia, comprehending the Ukraine, *i. e.* "the borders," or, in general, the three present governments of Kief, Tchernigof, and Novgorod-Sieverkoi; long separated from Russia, but again united to it in the year 1654. 3. White Russia, formerly denoting the present government of Smolensk, to which have been added the two governments of Polotsk and Mohilef, sometimes called the White Russian territory. 4. New Russia, denoting the large tracts of country near the Ukraine, towards Poland and the Turkish dominion, *viz.* New Servia and the province of St. Elizabeth, now belonging to the government of Ekaterinoslaf. But the Russian empire, in a more extended sense, includes not only the countries above-mentioned, but other regions, added to it by conquests and appropriations: such as, the kingdom of *Kazan*, the kingdom of *Astrakhan*, and the vast country of *Siberia*, which see respectively: the provinces on the shores of the Baltic, captured from the Swedes by Peter I. and for ever incorporated with the Russian empire by two treaties of peace, *viz.* Livonia, Esthonia, Finland, and Ingria, or the present governments of Riga, Revel, Vyborg, and St. Petersburg: the countries taken from Poland, now the governments of Polotsk and Mohilef, united to the empire by Catharine II.: the territory annexed by her to Russia in the peace concluded with the Turks in 1774: the Krim and the Cuban, or the province of Taurida and the government of Caucasus, united to the empire by that sovereign in 1783: the tributary islands in the eastern ocean, now added to Russia: the countries that have more recently submitted to the Russian supremacy, *viz.* Kartvelia or Kartalinia, &c.: the possessions in America, consisting partly of the islands, and partly of the continent of California, in which the principal establishment is called Donalek: and some other countries, incorporated with the empire at various periods, as the Kirghis-Kozaks, of the middle and little horde, who submitted themselves in 1731, and several others. From this survey it appears, that the amplitude of the Russian empire is far greater than that of the largest monarchy in ancient or modern times. Of its extent the empress, in 1783, thus expresses herself: "The Russian empire is distinguished on the globe by the extent of its territory, which reaches from the eastern borders of Kamtschatka to beyond the river Duna, which falls into the Baltic at Riga, comprising within its limits 165 degrees of longitude; extending from the mouths of the rivers Volga, Kuban, Don, and Dnieper, which fall into the Caspian, the Palus Mæotis, and the Euxine, as far as the frozen ocean, over 32° of latitude." If we take into the account some islands, which the empress has not mentioned, the Russian empire, says Mr. Tooke, according to the newest and best charts, will be found to extend from about the 43d to the 78th degree of N. latitude, and from the 39th to the 215th degree of longitude, thus including the islands lying in the eastern ocean. Without reckoning the islands, the empire extends in length above 9200 English miles, and in breadth 2400. The writer now cited gives the following comparison between the Roman empire, at the

the height of its grandeur, with that of Russia. The Roman empire contained about 1,600,000 square miles; or exactly as much as only the European part of Russia. Its greatest length, from the Euphrates to the western ocean, amounted to 3000 miles, and the greatest breadth, from the wall of Antoninus to the pillars of Hercules, 2000 miles; but if we take the length of the Russian empire, we shall find it to be, from Riga to Anadyrskoiofirog, 9684 miles, and thence to the haven of Peter and Paul, in Kamtschatka, 1750 more. Moreover, the possessions of the Romans extended somewhat short of 32 degrees of latitude; whereas Russia comprises 35½. The Russian empire received a fresh augmentation at the treaty of peace concluded with the Porte the 29th of December 1791; that is, the whole territory of Ochakof or Otchakov on the Bogue, as far as the Dnieller, which last-mentioned river is now settled to be the boundary for ever.

Russia has various frontiers: on the N. and E., omitting the establishment on the continent of America, it is bounded by seas; on the other sides, its limits are partly terra firma, partly seas, and here and there rivers, viz. to the W. Denmark, Sweden, and the Baltic; to the S. Courland, Poland, Turkey, the Euxine and the Caspian, Persia, China, and various tribes of almost savage, nomadic, or uncivilized nations. Other frontiers are fixed by treaty; as, with Denmark, concerning Lapland and Finland, in 1602; with China and the Mougols in 1727; with Persia in 1732, the river Terek being in some respects now regarded as the line of limitation; with Poland by various treaties, finally adjusted in 1795; with Sweden in 1721 and 1743; with the Turks by several treaties from 1739 to 1791; with Courland in 1783, which finally surrendered its independence in 1796. From Tchutзкаia Zemlia, northwards over Kamtschatka, the empire borders very nearly on America; being, by the latest observations, only separated from it by a strait of the sea, called Behring's or Cook's straits, not more than 175 English miles in breadth.

With regard to climate and temperature, the Russian empire has been divided into three large regions, viz. the region lying above the 60th degree, and extending to the 78th degree of N. latitude; that lying between 50° and 60°; and that lying to the S. of 50° and reaching to 43°. The first is the rudest and coldest, and contains the greater part of the governments of Irkutsk, Tobolsk, and Vologda, the entire governments of Archangel, Olonetz, and Vyborg, with part of those of Perm, Novgorod, and St. Peterburg. The second region, with regard to fertility, may be called temperate; and it comprehends the governments of St. Petersburg, Revel, Riga, Polotsk, Mohulef, Smolensk, Pfcove, Novgorod, Tver, Yaroslaf, Kostroma, Viætka, Perm, Kolyvan, a good portion of Irkutsk and Ufa, the governments of Moscow, Vladimir, Nishnei-Novgorod, Kazan, Kaluga, Tula, Riazan, Voronetch, Tambof, Penza, Simbirsk, Kursk, Orel, Novgorod-Sieverkoi, Tchernigof, and the greater part of Kief, Kharkof, and Saratof. The third region is the hot climate, yielding products, e. g. wine and silk, which the two former do not: in this lie Taurida, Ekaterinoflaf, the greater part of Caucasia, and a part of Kief, Kharkof, Voronetch, Saratof, Kolyvan, and Irkutsk. Mr. Hermann divides the empire more accurately by its climates into four regions; the first is the very cold region, from 60° to 78° N. lat., including Vyborg, Olonetz, Archangel, the greater part of Irkutsk, Tobolsk, and Vologda, and a part of Perm, Novgorod, and St. Peterburg; the second being the cold region from 55° to 60° N. lat., comprehending Revel, Riga, Polotsk, Pfcove, Tver, Moscow, Yaroslaf, Vladimir, Kostroma, Viætka, the greater

part of Perm and Kazan, and a part of Irkutsk, Kolyvan, Ufa, Simbirsk, Nishnei-Novgorod, Kaluga, and Smolensk: the third and moderate region extends from 50° to 55° N. lat. and includes Mohulef, Tchernigof, Orel, Kursk, Tula, Tambof, Penza, the greater part of Kief, Kharkof, Voronetch, Riazan, Saratof, Kaluga, Simbirsk, Ufa, Kolyvan, and a part of Irkutsk, Kazan, Nishnei-Novgorod, and Smolensk. The fourth or hot region reaches from 43° to 50° N. lat. and contains Taurida, Ekaterinoflaf, the greater part of Caucasia, and a part of Kief, Kharkof, Voronetch, Saratof, Ufa, Kolyvan, and Irkutsk. In many districts of the first region there is hardly any summer; the spring has in general much frost, snow, and rain; the winter is always severe. In the second region the summer is in many parts short, and yet in most of them so warm and the days so long, that the fruits of the earth usually come to perfect maturity, in a much shorter space of time than elsewhere; the winter too, particularly in the governments of Irkutsk, Tobolsk, Perm, Viætka, &c. is for the most part very severe. In the third region there are very extensive districts, e. g. in the governments of Irkutsk, Kolyvan, and Ufa, where the winter is also long and cold, which is chiefly owing to the lofty mountains with which they abound; but the governments in the European division of Russia, lying under this meridian, mostly enjoy a short and tolerably temperate winter, and a fine warm summer. In the fourth region the winter is short, the summer warm, often hot, and in many parts very dry.

The whole Russian territory consists at present of fifty alike-organized provinces, called governments or viceroalties. Each government is again divided into several circles; and some of the largest are farther distributed into districts. In each circle is a circle-town, where the circle-administration has its seat, and one of these circle-towns is at the same time the government-town, in which the governor-general and the principal officers reside, and by which the whole government is usually denominated. Besides these fifty governments, there are two more countries, having a military civil constitution, viz. the country of the Donskoy-Kozaks, and the country of the Euxine-Kozaks. (See COSSACKS.) The whole number of provinces is therefore fifty-two; and, moreover, the Georgian states Karduelia and Kakhetty, several petty districts in the parts of Caucasia, together with the country of the Kirghis-Kozaks, are to be reckoned among the countries under the protection and in the dependence of Russia.

*History of the Russian Empire.*—Although no other European empire has been so frequently and so well described in the three last centuries by foreign travellers as the Russian; yet neither did any other remain so long unknown to the civilized nations of our quarter of the globe. This fact may justly excite our surprize, if we consider, that so early as the thirteenth century, the adventurers and ambassadors, who either visited for private purposes, or were dispatched by their superiors to the courts and territories of the Tchingiskandes, partly took their route through Russia (for instance, Carpin and his attendants: see Voyage de Jean du Plan Carpin, chap. 1. in the Recueil de Bergeron): that in the same century the Hanse towns established numerous factories and a flourishing commerce, both at Novgorod and Plesco, and the Teutonic knights had founded a powerful state on the borders of Russia: that about the same period the Genoese, Venetians, and other Italian republics, occupied with colonies the coasts of the Euxine, and the rivers that flow into that sea, or at least navigated them, and from these colonies and coasts carried on an extensive trade with all the countries far and near: that even long before this, enterprising

prising Danes and Normanni, for the purposes either of traffic or depredation, explored the harbours of the White sea, and even the desert shores of the great northern ocean, abounding in costly furs : and that finally, Ivan the Threatening, and his son Vassilli Ivanovitch, waged frequent wars with the Poles, the Swedes, and the Teutonic knights, and had frequent correspondence by embassies, not only with their neighbours, but likewise with distant princes and populations. Whether the warriors, merchants, and artists who had a view of Russia, neglected to write down their observations, or their written remarks were never published ; the fact is, that as far down as the commencement of the sixteenth century, the learned of Europe knew much less of Russia than we at present know of New Holland. It is likewise often difficult to discover from the earliest writers on Russia, when it was they wrote, or when their writings were first committed to the press ; and though we should happily find out both the one and the other, we are not unfrequently at a loss, whether to arrange these ancient journalists and geographers according to the time when they wrote, or that in which their works were published.

The first particular accounts of Russia are found in the " Viaggio di Messer Jofafa Barbaro alla Tana," and in the " Viaggio del magnifico M. Ambrosio Contarini," both in the second volume of the " Raccolta" of Ramusio. It is scarcely probable that these travels were printed earlier than the collection of Ramusio, since they are quoted by no author prior to the middle of the sixteenth century. Barbaro travelled in 1436, as a merchant alla Tana, or to the Crimea, and remained there sixteen years. He speaks only in the two last chapters of Russia, and of the Tartarian countries which lay to the south and to the east of Russia ; particularly of Citracan, or Astrachan ; and of Casan, which city he describes as the principal mart of the trade in furs, which in his opinion were brought thither from Zagatai and Moxia. Barbaro must have wrote his journey long after his return from the Crim, as he remarks that the Russians had conquered Casan and Novgorod. Contarini travelled, in 1483, in quality of ambassador from his republic, through Poland and the Ukraine to the court of Persia, and returned, in 1487, across the Caspian, by Astrachan, and through Russia proper. It is curious enough that he speaks of a *Rossia bassa* and *alta*, and of a *gran Rossia bianca*. Of Novgorod he says : " la qual confina quasi con la Francia, et con la Almagna alta."

A great part of the Russian empire was anciently inhabited towards the N.E. and N. by a people of Finnish origin, perhaps descended from the ancient Scythians. Towards the N.W. were tribes consisting of a motley race of Sauromates and Grecian colonists ; and from them are descended the modern Lithuanians, Lettovians, Livonians, and Courlanders ; as were also the ancient Prussians. The whole southern part of Russia, even to the Crimea or Crimea, was for some time inhabited by Goths ; and between the Volga, the Don, and mount Caucasus, was a nation descended from the Medes, called Sauromates, that is, the northern Medes. In process of time, when barbarian nations issued in swarms from the E., and some of the different tribes of Goths had, since the middle of the third century, penetrated into the western regions of the Roman empire ; some of the Sauromates were under the necessity of retiring farther towards the N. and the W. The same political constitution which is now prevalent, existed at that remote period. Each individual of the nation was either master or slave. The various tribes which occupied the country derived their appellation from some river, town, or district ; and from the more modern Varagian Rossi, the Russians,

it is said, about the year 862, received their name. No country in the globe contains such a mixture and diversity of inhabitants : each distinct nation having its own language, in some cases debased and corrupted, and retaining, more or less, its own religion and manners ; while the generality of the main stems bear in their bodily structure, and in the features of their faces, the distinctive impression of their descent, which neither time nor commixture with other nations has been able altogether to efface.

The aborigines of Russia were *Finns* and *Slavonians*, see each respectively. Of the Slavonians, who inhabited the country about the Dnieper and the Upper Don, some, oppressed by the Bulgarians, spread themselves farther northward on the Dnieper, and constructed Kief, while another colony penetrated up the Volkhof, and laid the foundation of Novgorod. After a dark period of more than 100 years, the Slavonians appear again among the Finns, and at this time the Russian state received its origin from the Scandinavians or Northmanni. The Slavonian settlers, both on the Volkhof and the Dnieper, were oppressed by two hostile nations, *viz.* the Khazares from the Euxine, and the Varagians, Varingians, or Northmanni from the Baltic. (See KHAZARES and VARAGIANS.) In the ninth century, the Varagians conquered from the Russians, who were a kindred north-gothic people, first mentioned in the year 839, and belonging to the Varagian race, and of course originally Normanns or Scandinavians, the modern districts of Revel, St. Petersburg, and Archangel, and subjected the Slavonians, Krivitsches, Tschudes, Vessenians and Merænes, various tribes, partly Slavonians and partly Finns, to a tribute. The Russians retired to Finland and Karelia ; but at length the Slavonians, aided by the other tribes just mentioned, expelled the Varagians, and formed themselves at the lake Ilmen, near Novgorod, into a federative democratical republic. After experience of the imperfection of this constitution, and finding it productive of internal disturbances, the five united nations resolved to call in the Russians for the purpose of restoring tranquillity, and affording them protection ; and with this view they voluntarily offered to resign the sovereignty to them. The Russian prince Rurik, with his brothers Sineus and Truvor, accepted the invitation. Rurik, having collected together all his people, came in the year 862 to the mouth of the Volkhof, and assumed the government of the newly erected state ; which, from its first formation, consisted of six several tribes, *viz.* Slavonian, Finnish, and Varagian, extending over the regions of the present governments of Riga, Revel, Polotsk, Pskove, Vyborg, St. Petersburg, Novgorod, Smolensk, Olonetz, Archangel, Vladimir, Yaroslaf, Kostroma, and Vologda. Whilst the Varagians, under Rurik, composed the predominant part, the Slavonians and Russians were soon blended into one nation ; and though the name of the latter was transferred to the whole nation, yet the Slavonian language and manners retained the superiority, that people being considered as the most prevalent, both with regard to number and civilization. Rurik, fixing his residence at Staraya Ladoga, assumed the title of grand-prince ; and when both his brothers died childless, he reunited their territories with his own, and in the fourth year of his reign, removed his residence from Old Ladoga to Novgorod, which from that time became the capital of the Russian monarchy. Soon after the elevation and establishment of Rurik, the Slavonians on the Dnieper, being oppressed by the Khazares, besought Rurik to give them a prince of his own race ; and he accordingly sent his step-son Oikold, who subdued the Khazares, and founded at Kief the second Slavo-Russian dominion, dependent on the Novgorodian empire. Oleg, the immediate

immediate successor of Rurik, united Kief with the Russian territory, and appointed this second Slavonian family seat to be his residence and the capital of the country. Under the following reigns, the power of the empire rapidly increased. Russian armies appeared before the gates of Constantinople; many nations were rendered tributary; the Russians carried on a regular commerce to the coasts of the Euxine; they built cities, and not only embellished but gave laws to such as already existed. On the death of Vladimir the Great, in the year 1015, who embraced the Christian religion, and introduced it into Russia, the progress of the nation was checked by the partition of its territory among his twelve sons. This was followed by a variety of sanguinary contentions, till at length there arose a third state, *viz.* White Russia, or Vladimir. Of these three states, *viz.* Vladimir, Kief, and Novgorod, the principal was Vladimir, and Suzdal was its capital. This distinction afterwards devolved on Vladimir; and finally on Moscow, a city which was founded in the year 1147, by George I. In the year 1237, the Mongoles and Tartars, who under their khan Tschingis had united themselves into a powerful state at the beginning of the 13th century, and subjected the greater part of Asia, put themselves under the conduct of his descendant Batu, khan of Kaptchak, and fell upon Southern Russia, where they founded a formal sovereignty. The Tartars, having effected their conquest, numbered the people in the principalities, imposed on them a heavy tribute, and thus riveted the oppressive yoke of foreign sovereignty which the Russians endured for upwards of 200 years.

Whoever has studied the Russian history with attention, must naturally be surprized that the nation, in consequence of the numerous and formidable revolutions which it underwent, was not utterly demolished or dispersed, their dominion entirely subverted, and their very name, as has been the case with so many other nations, totally effaced. The Russian nation, however, not only weathered out all the storms, which so frequently menaced its dissolution, but rose, as if refreshed with juvenile vigour, extended its gigantic arms on every side, vanquished all its hostile neighbours, and at a very early period of its greatness crossed the mountains, which for immemorial ages had been styled by their inhabitants the girdle of the globe, and there, as in a new world, progressively made conquests, no less for geography and natural history, than for their immense domain.

In 1462, Ivan Vassilievitch I. ascended the throne of Moscow, and after a reign of fourteen years, refused obedience to the Tartars, and by a series of victories, gained possession of the Tartarian kingdom of Kazan, and reduced its sovereign to a state of tributary vassalage. In 1477, the republic of Novgorod submitted to the force of his arms, and a similar fate befel the principalities of Pskov and Tver. Lithuania lost a considerable part of its territory. The princes of Severia voluntarily surrendered; and the increasing power of Ivan was withstood only by the Teutonic order in Livonia. Under his successor Kazan was lost for a short time; but Smolensk was incorporated into the Russian state. Ivan Vassilievitch II. at length burst the last shackles of the Mongole-Tartarian sovereignty. The entire conquest of Kazan was completed in seven years, the capital of the kingdom surrendering in 1552. Two years afterwards, Astrachan became a Russian province: and Ivan advanced into Caucasus, and subdued the whole Kabardey. Although the Ottoman Turks, aided by the Tartars of the Krim, ravaged the capital of Russia, this disaster was amply counterbalanced by the channel opened for maritime commerce by way of Archangel, and by the conquest of Siberia, events which date their commencement from the reign

of Ivan, but which owed their completion to his successors. As others state these events, Ivan III., surnamed the Threatening, was the first who, towards the latter end of the fifteenth century, began to demolish this baneful oligarchy, and to throw off the yoke of the Tartars. The most considerable annexation he procured to his empire consisted in the reduction of Novgorod, and the northern provinces, which ages ago had been conquered by the Novgorodians, and retained under their dominion. His son and his grandson Vassilie Ivanovitch and Ivan Vassilievitch the Terrible, completed the grand project, which the father and grandfather had left for their successors. Under the reign of Vassilie Ivanovitch, baron Herberstein laid down the first perspicuous geography of the Russian empire, according to which we shall describe the boundaries of it towards the latter end of the fifteenth, and the commencement of the sixteenth centuries.

Herberstein uses the term Russia in a two-fold acceptance. By the one he understands all those countries that were inhabited by Russians; and in this larger sense he even comprehends the king of Poland and the grand duke of Lithuania among the Russian princes, since both of them possessed territories that were occupied by Russians. In the more contracted import, that author comprises simply the countries subject to the grand prince of Moscow. In the description of this proper Russia, taking his departure from Moscow, he first mentions the eastern and southern, and then the western and northern provinces.

Eastward, therefore, of the province of Moscow, the grand prince of Russia possessed the provinces of Vladimir, Nishnei-Novgorod, and Riazan; the river Sura forming the boundary between the Russian and Casanian territories. (Sura fluvius Moscæ, et Casanenſis regis dominium dividit, page 65.) Towards the south-east, during the reign of Ivan III. the Russian confines reached only about a day's journey from the city of Riazan; for Contarini arrived at the city Riazan the day after he entered the Russian territory. (Ramus. ii. 122. fol. b.) To the south, Tula was the last Russian city towards the Tartarian steppes (Herberst. p. 66. Tulla—est ultimum oppidum ad campeſtria deferta); and somewhat farther to the west was Kaluga, the fortified city, where the grand prince annually assembled his troops against the incursions of the Crimean Tartars. (Ibid. p. 68.) Towards the south-west, Vassilie Ivanovitch first conquered the principality of Novgorod Sieverſkoi, which at that time comprehended also Tcheruigof, and a part of the present government of Orel. (Ibid. 63—70.) Towards the west, Smolensk, which province Vassilie Ivanovitch, in 1514, severed from Poland or Lithuania, Pskov, and a part of the present Petersburg government, to the mouth of the Narova, formed the boundary. To the north of Moscow lay, lastly, the provinces Tver, Great Novgorod, Yaroslaf, Kostroma, and the provinces formerly subject to the Novgorodians, namely, Vologda, Ustiug, Viatka, Perm, and Dvina.

Reckoning the principalities specified by Herberstein to the division of the governments and viceroalties made by Catharine II. then the empire subject to the grand prince Vassilie Ivanovitch, excepting Moscow and a part of the Petersburg government, comprised only those of Pskov, Tver, Novgorod, Archangel, Vologda, Yaroslaf, Kostroma, Viatka, Perm, Smolensk, Tchernigof, Novgorod Sieverſkoi, Orel, Kaluga, Tula, Riazan, Vladimir, and Nishnei-Novgorod. Short of the present number of viceroalties by those of Petersburg almost entirely, then those of Viborg, Revel, Riga, Olonetz, at least in part, Tobolsk, Polotsk, Mohilef, Kharkof, Kurſk,

Kursk, Kazan, Simbirsk, Penza, Tambof, Voronetz, Saratof, Ufa, Kolyvan, Irkutsk, Minsk, Iftiaflaf, Brazlau, Kief, Ekaterinoflaf, Caucafus, and Taurida, together with the country of the Don Cossacks, and the provinces which fell to Russia on the last partition of Poland.

Ivan the Terrible continued the aggrandizement of the empire, of which his father and grandfather had laid the foundation, with equal zeal and success. He conquered, in 1552 and 1554, Kazan and Astrachan, and united the countries dependent on those cities for ever with his empire. It was during his reign that a band of Don Cossacks, whom he had driven as robbers from the inferior Volga, forced their passage across the Uralian mountains, overturned the dominion of the Tartars on the Tobol and Irtysh, and, unknown to the grand prince, conquered the north-western districts of Siberia to the last-mentioned river. Though it cannot be said that the Russian tzars had neglected to make conquests in the northern Asia; it may, nevertheless, be affirmed, in a certain sense, that the conquest of Siberia was completed of itself in nearly the same manner in which it was begun. The court of Moscow undoubtedly listened with encouraging attention to the advantageous proposals that were made respecting the extension and fortification of the Siberian districts, and royally rewarded the persons who, by their prudence and bravery, had deserved so well of the empire. The czar sent, or at least agreed to the reinforcements that were wanted for the farther prosecution, or the defence of the acquisitions, now that they were made. These reinforcements were, however, generally so small, that in Moscow, much less abroad, they were scarcely remarked. The hopes of obtaining riches either by a fortunate chance, or by extortions practised on the unarmed tribes that were found inhabiting the steppes and wilds of Siberia, annually allured thousands of bold hunters and warriors into those parts; and these adventurers, spurred on by their insatiable avarice and unbounded licentiousness, were perpetually exploring new regions and populations, which were not yet exhausted and plundered of their all. Thus it happened, that about a century after Yermak had destroyed the empire of the Tartars upon the Irtysh, almost the whole of that prodigious tract of country was subdued at a far less expence of blood and treasure than the smallest of the western and northern provinces which had hitherto been conquered had cost, or, as was afterwards seen, those which then remained to be subdued.

Feodor, the son and immediate successor of Ivan the Terrible, abandoned his claim to Esthonia, and in return forced from Sweden in 1594, the cession of Ingria and Karelia. By Feodor's death, in 1598, the dynasty of Rurik became extinct; and during the subsequent interregnum, many pretenders, under the name of Demetrius, invlved the empire in confusion, till, in 1613, Mikhaïla Romanof, or Michael Feodorowitz, of the dynasty of Romanow, descended in the female line from Ivan IV. was elected sovereign, and by large sacrifices purchased the repose of his empire. To the Swedes he was obliged to relinquish Ingria and Karelia, and to the Poles, Smolensk, Severia, and Tchernigof, and to make a formal renunciation of all claims upon Livonia, Esthonia, and Courland. From that period to the present day, Russia has not only been gaining its ancient possessions, but so far extending and enlarging them, that the present circumference of the empire has no parallel in the history of the world. Alexey, or Alexis, the son and successor of Michael, not only reconquered the countries ceded by his father to the Poles, but also reduced Kief and the Ukraine on the E. side of

the Dnieper, in 1655, to a re-union with the parent state of the Slavo-Russian nation. His son, Peter I., "the creator of modern Russia," acquired to his empire in 1721, by a twenty years' war with Sweden, the provinces on the shores of the Baltic, which had occasioned bloody contentions among the northern powers for many centuries: Livonia, Esthonia, Ingria, and a part of Kexholm and Karelia, were subjected to the Russian sceptre, thus adding to the Russian empire great advantages for commerce, and a respectable rank among the principal European powers. Catharine II. aggrandized Russia both within and without, by a reform of its government, and by several successful wars. She obtained from the Porte, in 1774, the possession of the city of Azof, with its territory; and for the security of the Russian navigation on the Euxine, the forts of Kinburn, Kertsch, and Yenicaly in the peninsula of the Crimea. In 1783 the whole province became, by treaty, a Russian government; and recovered its ancient name of the Tauridan Chersonese. Russia also, by the same convention, enlarged her borders to the south by the Kuban, where at present the Caucasian mountains form the boundary of the Russian dominion. Afterwards the Porte was compelled to surrender a considerable tract of country on the shores of the Euxine, between the Bogue and the Dnieper. In the disgraceful partition of Poland, Catharine obtained for her share, in 1773, the four Lithuanian voivodeships of Smolensk, Vitepsk, Miltislaw, and Polish Livonia, with a part of the voivodeships of Polotsk and Minsk. An unprosperous war terminated in 1793, with the loss of the fertile provinces of the Lesser Poland and Lithuania; and at length the capital of the kingdom fell into the hands of the Russians; its political existence was annihilated, and in 1796 the last vestiges of it were lost in the confines of the bordering states. One consequence of the annihilation of Poland was the acquisition of the duchies of Courland and Semigallia, including the circle of Pilten, which, on the dissolution of their feudal connection with the republic, by a resolution of the states of the country, submitted themselves unconditionally in 1795 to the sceptre of the empress.

Catharine extended her territory, by the mild authority of her laws, and the methods of civilization which she adopted, as well as by her conquests and treaties. Accordingly the czar of Kartvelia and Kakhetty put himself under the protection of the Russian empire, by acknowledging, in 1783, the supremacy of its monarch. She also invited people from all countries to settle in her dominions, and thus established numerous colonies. She reduced a multitude of tributary nations dwelling in the interior of Siberia to submit to her laws. She set on foot and encouraged several voyages of discovery, which obtained for the Russian empire a new sovereignty in the eastern ocean, and on the western coast of America.

The brilliant conquests of Catharine may, indeed, immortalize her fame as a conqueror; but they alone will never render the memory of that accomplished and sagacious monarch beloved and blessed. Cordial affection and admiration are the proper tribute both of contemporaries and posterity, due only to her as the wise and benign legislatrix, instructress, and patroness of her numerous populations and countries. Thousands of persons, to whose judgment even upright and excellent sovereigns cannot be indifferent, lament at present, and will lament to latest ages, that the emotions of affection and admiration, so congenial to the heart with which the exalted legislatrix, instructress, and patroness of the nations obedient to the Russian sceptre has inspired, and ever will inspire them, are painfully disturbed

turbed and abated, either by the recollection of the blood which one half of her conquests cost, or the maxims that were followed in obtaining possession of the other.

Researches respecting the extent and dimensions of countries would be of far greater value than can at present be allowed them, if the internal strength of empires increased in equal ratio with their extension, or the real happiness of their inhabitants with both. Russia affords the most convincing proof that this is not the case. No European nation ever ruled over countries of such vast extent as the Russian; and yet there have been, and still are in Europe, several nations exceeding the Russian in population, or at least in power and well-being. The statements of the magnitude of the Russian empire lose greatly of their interest by differing so widely from each other. Le Clerc gives to the Russian empire a superficial content of 949,375 leagues, and censures the historian l'Évêque for having erred in his statement by at least 424,375 leagues. The German geographers have not so great a discrepancy in their account as the French. In the mean time, between those who set it down at the least, and those who assign to it the greatest number, there is a prodigious interval, an interval which Germany and France together could not fill up. We mean France before the revolution. Three hundred thousand square geographic miles compose the least, three hundred and thirty thousand the greatest extension which German authors have assigned to the Russian empire.

Of those tribes called Kozaks or Cossacks, which are of Russian origin, we have given a brief account under the article *COSSACKS*. Of the three Slavonian nations, properly so called, that are inhabitants of the Russian empire, next to the principal nation, the *Poles* are the most numerous. These, it is said, at the same time with the Russian Slavi, and on the same occasion, came from the Danube to the Vistula. Their state, now nearly extinct, was probably founded in the ninth century; and they sprung from the same stock with the Russians. According to the present state of the Russian empire, the Poles form a very considerable part of the aggregate population. They may be found, in an immense multitude, in the governments of Polotsk, Mohilef, Minsk, Brazlau, Vofnefsensk, Podolia, Volhynia, Vilna, and Slonimsk; and in smaller numbers, as colonists, in the circle of Selenghinsk, on the Irtsch, and in various other parts of the empire. The third Slavonian nation within the borders of Russia is composed of the people called *Servians* or *Serbes*. (See *SERVIANS*.) Besides those tribes which we have already enumerated, there are two others in the Russian empire, who are supposed to be related to the Slavi: these are the Lithuanians and the Lettish. (See *LITHUANIA* and *LETTES*.) For an account of the *Kalmucks*, *Mandshures*, *Mongoles*, and *Tartars*, as composing primitive stocks of the nations dwelling in Russia; see these several articles respectively. In the Russian empire there are also some nations whose origin is utterly uncertain. Mr. Tooke reduces them to two classes, one comprising the *Samoyedian*, and the other the eastern *Siberian* nations. (See *SAMOYEDS* and *SIBERIA*.) Of the European nations, some bodies of which are dispersed through the Russian empire, the most numerous are the German. In the governments of Riga, Revel, and Courland, they form the most considerable, though not the most numerous, part of the inhabitants. The Germans residing in the government of Riga amount, according to the latest enumeration, to 30,000, and those in that of Revel to 15,000; and in Courland they are thought to be still more numerous. In Moscow and St. Peterburg they live by thousands; in the latter alone they are known to be

upwards of 17,000. As colonists, properly so called, many thousand German families came, in 1763, into the governments of St. Peterburg, Saratof, Veronetch, and Tchernigof, as settlers, the number of whom, since the year 1783, is much increased by new settlements in the government of Ekaterinoslaf, and in the province of Taurida. All these, and the multitude of such as live separately about the empire, taken together, may, as Mr. Tooke suggests, probably far exceed 100,000. Of the other European nations, there are only detached colonies, especially in the large towns. In the governments of Vyborg and Revel, and in some of the islands of the Baltic, there are Swedes, but not amounting to a very considerable number. The islands Vorms and Rugen, in the Baltic, are partly inhabited by Danes, but they are most numerous in Moscow and St. Peterburg, and some of the large towns. In most of the sea-ports there are Englishmen, who make no long stay, but return to their native country as soon as their affairs permit. French and Italians are also dispersed over the whole empire. In Little Russia, at Nethin, in the government of Tchernigof, in that of Ekaterinoslaf, and in Taurida, the Greeks form some respectable colonies. In the government of Ekaterinoslaf there are also Albanians, Moldavians, Valakhians, and Arnauts, though their number is not great. The Ottoman Turks are, in a great degree, dispersed; but they are found together in small numbers at Orenburg, in the former Otchakof steppe, and in some other places. In the districts of Astrachan and Orenburg there are many Persians, and on the Kamma there is a colony of Persians and Arabs. The Armenians are numerous in the towns of Orenburg, Kitzliar, Mosdok, St. Peterburg, and Moscow; but in the governments of Caucasus and Ekaterinoslaf they compose a colony consisting of some thousands. The town Nachitschevan, on the Don, is almost wholly inhabited by them. In Astrachan and Kitzliar are settlements of Indians. The Jews are numerous in some of the provinces, particularly those of Poland, now annexed to the Russian empire, and in Taurida, where they are partly fixed as ancient inhabitants. Gypsies are found strolling in large companies in the provinces both of Great and Little Russia. Upon the whole, Mr. Tooke observes, that the inhabitants of the Russian empire form at least 80 distinct nations, differing essentially in lineage, and also in manners and language.

*Climate, Weather, and natural Qualities of the Soil of Russia.*—As to the soil as well as the climate, there is a great diversity in the different provinces of the Russian empire. Some tracts of land in Great and Little Russia, in the provinces bordering on the Baltic, and many others, are kept in constant cultivation and tillage. In other districts, *e. g.* in Little Russia, about the Don, &c. the land is only cultivated occasionally; and again in other parts of the empire, lands fit for agriculture are left wholly unemployed, for want of labourers. The quality of the soil is very different in different tracts; in Livonia and Esthonia, good fields yield 8, 10, and 12-fold, and, in some cases, 16, or more than 20-fold; but in different ground about 3. The harvests about the Don are commonly 10-fold; but towards Tomsk, on the Tshumush, and in the whole region between the Oby and the Tom, many fields afford an increase of 25 to 30-fold; and at Krasnoiarisk a crop has not been known to fail; of winter corn they reap 8, of barley 12, and of oats 20-fold. In Little Russia, on the Don, and in many other places, the soil is sufficiently fertile, without manure. This is also the case in a great part of Siberia, *e. g.* on the Samara; on the Ufa, in the country of the Bashkirs; here and there in the Baraba; and also on the Kamma, in the government of Ietzk; on the Oby near Barnaul, at Krasnoiarisk, and on the Selenga.

All travellers agree in praising the salubrity of the atmosphere in Russia, and the absence or infrequency of several diseases with which the other countries of Europe are visited, arising from it. Herberstein and his followers, from the general healthiness of the Russian climate, have explained this remarkable fact: that, from time immemorial, the plague has never communicated itself from the sources of the Don to the north and east; which opinion, however, has been confuted, even in ancient times, by several dreadful pestilences, and likewise in the last century, by the formidable plague which, in 1770—1772, raged in the city and territory of Moscow. Since the districts of the Lower Don and Dnieper, and those between the Dnieper and the Dniester, have been incorporated with the Russian empire; the country of the Don Cossacks, and what was formerly called Polish Ukraine, form an exception to the justly boasted salubrity of the climate of European Russia. Almost every year thousands of persons are carried off by all kinds of ardent and putrid fevers, dysenteries, inflammations of the chest, pleuritis, &c. from July to the beginning of winter, especially in those parts which are surrounded with fetid morasses, or have no other than stagnant and putrescent water.

While, upon the whole, they extol the salubrity of the Russian climate, they, in general, complain of the intense cold of the winter, and the equally excessive heat of the summer, which, in the northern and central Russia, very often prove destructive to men and beasts, no less than to the fruits of the earth. Almost all travellers adduce the same allegations, or instances of the insufferable heats and frosts of the Russian empire. The winter, say Herberstein and his followers, lasts from six to eight months. During that season, all the rivers and lakes are covered with all-thick ice, and the ground with all-deep snow. Where the ground is not covered, it is rent in wide and deep chaps by the winter cold, as in the milder parts of Europe by long continued summer drought and heat. In the coldest days, on first going out of the warm apartments into the open air, the breath is taken away, or contracted almost to suffocation. Spittle ejected is converted into ice before it reaches the earth; and if we touch metal with moist hands, the skin is left adhesive to it, as though the metal were glowing hot, and the same sensation is experienced from the contact. With the utmost precaution it nevertheless frequently happens, that those who take only a short walk, in a few minutes have their nose, ears, or fingers frozen. Men and cattle bringing provisions to town are often frozen to death. Ravenous and other birds fall dead to the ground, and fruit-trees are riven by the piercing frost. It is affirmed by Gæteeris, pp. 88, 89, that it sometimes happens that flesh and fish, which have been boiling and roasting more than an hour, on being cut up on table, were still frozen within. The same author relates that the beards of himself and others were hard frozen to the bed-clothes while asleep. The greatest advantage arising from long and severe winters in Russia is this; that it levels all roads, and opens them in every direction, so that travelling from one place to another is incredibly rapid and cheap; therefore, even in ancient times, when many canals were not yet dug, many roads and bridges not constructed, and many swamps not drained, the winter, still more than at present, was the proper season for commerce and the transport of commodities. Whereas, no sooner has the vernal sun dissolved the incrustation of the waters and the land, but at once the rivers and streams overflow their banks, converting the lower plains and vallies into lakes or morasses. Within a few days after the snow has disappeared, the forests and trees are clothed with beautiful foliage, and the ploughed lands, meads, and pasture-grounds, with the most luxuriant corn and herbage,

which, owing to the humidity of the soil, and the rapidly increasing ardours, shoot upwards with an almost visible growth. The times of sowing and reaping, therefore, border on each other in Russia much nearer than in other European countries. Violent rains, boisterous winds, and continued fogs, are more frequent than thunder-storms, as immoderate, or late frosts, are oftener injurious than long droughts. Sometimes, however, Russia experiences such hot and dry summers, that fields of standing corn and forests take fire, so that entire provinces are filled with noxious smoke, and in some sort darkened by it. Among the principal annoyances of the hot seasons, are the innumerable swarms of musquitos, from which no rest is to be had night or day, and the cold nights that not unfrequently succeed to sultry days.

Russia being generally a level country, or at most only rising to moderate hills, it is somewhat curious that, though destitute of mountains, it contains more forests, lakes, and rivers, more brooks and running springs, than any other territory in Europe.

The north-eastern provinces, from the Volga to the Ural, are described by former travellers as a country for the most part covered with inexorable forests, and that even where it is cultivated, it strikes the eye as having been not very long since clothed with wood. Herberstein, p. 61, speaks thus even of the province of Moscow: "Totam porro regionem non ita diu admodum sylvofam fuisse, ex magnis arborum truncis, qui etiamnum extant, apparet." "Il est vrai," says Miège, "qu'il est tellement plein de forêts, que dans l'espace de 500 lieues, que nous fimes à travers ce pays là, nous en eumes toujours en vue, quoique ce fut la partie la mieux peuplée du pays." Russia is, even at present, far more woody than any other European countries. The Volchonkoi forest, through which the road lies from Viazma to Moscow, extends on all sides to unknown distances; and in this forest it is said, that, even in the last century, numerous colonies were discovered, which, from their origin, had been utterly unknown, not only to the government, but even to the nearest inhabitants. Of such colonies several may probably still exist in the prodigious forests with which the districts of Olonetz, Archangel, Perm, and other northern districts are covered. Even the road between Moscow and Petersburg runs mostly through an uninterrupted succession of woodland, in which villages are rarely seen. The forests of Russia consist chiefly of cedars, pines, firs, lindens, and birch; and the shores of the Volga, the Occa, the Don and its tributary rivers, are adorned with vast forests of oak, from which the ship-timber is conveyed to the ports of the Baltic, and to the wharfs of the Don and the Euxine. The regions between the inferior Volga, between the Don and Dnieper and Dniester, have fewer or even no woods at all, and the inhabitants are obliged, in many places, to dress their victuals with dried cow-dung.

It would be in vain to attempt at particularizing the lakes, pools, and marshes, the rivers, brooks, and springs which are said by the ancient travellers to be innumerable even to the inhabitants themselves. Those who came from Poland, or Livonia, represent travelling through Russia as extremely perilous, not only on account of wolves and robbers, but from the badness of the roads, and the miserable state of the bridges. When people of quality were going a journey, orders were previously sent to the country-folks of the parts adjacent, to make the roads and bridges in some degree passable. The high roads are now, in many parts of Russia, as fine as in other European countries. If the wooden bridges are in some places badly maintained, and from the defect of here or there a balk are inconvenient and troublesome to the traveller; they do not, however, so often endanger his neck. The roads are at least sufficiently wide, and every where provided

vided with verst-posts. See Coxe's Travels, vol. i. where the road between Petersburg and Moscow is described.

Those who have gone from Archangel up the Dwina and the Yug by ship, and then generally in sledges from Vologda to Moscow, unanimously affirm, that nowhere is more convenient and pleasant travelling than in Russia; the eye being incessantly delighted by the alternation of magnificent forests, rich pastures and corn-fields, but principally by the inexhaustible abundance of running waters. (Fletcher, pp. 414, 415.) This latter commendation is, however, more fitly applicable to the northern than to the midland and southern parts of Russia, since in these the rivers have a slow current, and in summer are nearly stagnant; so that from Moscow quite to the Crimea scarcely any other than bad or indifferent spring-water is found. Suyef, p. 7.

On no topic are travellers more agreed, than in extolling the fertility of most of the Russian provinces. The soil, they inform us, consists generally of a black, fat mould, which produces all kinds of corn and grain, orchard fruits and garden vegetables, as also hemp and flax, in the greatest abundance; and, in many places, even without needing manure. The meadows and pasture-grounds feed incredible droves and herds both of large and small cattle: the forests are the haunts of an unspeakable quantity of not only the choicest species of game, but likewise of such animals as yield furs, which are every where eagerly sought after: the lakes, ponds, rivers, and brooks, in short, nourish a far greater variety of the most delicious kinds of fish, than all the other countries of our quarter of the globe taken together.

With respect to fertility of soil, the preference is generally given to the province of Vladimir, or somewhat rather, perhaps, to that of Riazan. The soil is, in the former of these provinces, of such fecundity, that not unfrequently from one bushel of sowing a produce of from twenty to thirty bushels is obtained. Still more prolific is the province of Riazan; where, according to report, very often one single grain of wheat will shoot out two or more straws, and they so thick and strongly grown together, that a horse cannot easily break his way through, and growse can with difficulty rise from among them. These provinces likewise produce honey, wax, fish, fowl, and all sorts of game, in the greatest profusion, and of the best quality; even the human inhabitants of them are bolder and more warlike than other Russians. If any one should think proper to put the Ukraine and the country of the Don Cossacks in competition with these two provinces, we have only to allege against it, that, indeed, in many parts of the Ukraine no manure at all is used; because if it were, it would either burn up the farina fecundans of the seed, or only produce enormous straws and foliage, destitute of ears and fruits. The stalks of the Ukraine corn are so tall and thick, that they are more like reed-stems than corn-straws.

Honey and wax are sought for in hollow trees, where the wild bees deposit their treasures, or in trunks of trees excavated for the purpose of serving as hives, which the boors fence with wires, to preserve them from the depredations of the bears. Several authors repeat the story, which Jovius heard of the ambassador Demetrius; that a boor once looking for honey in the forest, fell up to the neck in a hoard of it in a large hollow tree, whence, after passing a couple of days in that sweet situation, he was extricated at last by catching hold of the hind legs of a huge bear.

No country of Europe abounds so much as Russia in fish and game, particularly in the choicest wild-fowl, viz. the woodcock, the heath-cock, the pheasant, the partridge, the bustard, the snipe, &c. Cavear was already a principal article of commerce in the 16th century, and was exported by the French, Dutch, and English to Italy and France, having

been first brought hither by Capt. Chancellor, in the reign of queen Elizabeth. It is mentioned by Shakspeare in his Hamlet: "Cavear to the multitude." But we must break off. To enter into details of wild and tame animals, of mines and metals, of edible roots and vegetables, of orchard fruits, of flowers and grasses, of wild herbs and berries, of the cheapness of the several necessaries of life, and the gradual increase of their prices, would swell this article beyond all proper bounds. We must, therefore, content ourselves with referring the reader for these and other particulars to the travellers who have given their observations to the public; such as Herberlein, Jovius, Olearius, Petreius, Margaret, Dr. Fletcher, Muller, the two Gmelins, Le Bruyn, Gæteeris, Cook, Korb, Tanner, Kupel, Herrmann, Hamard, Guagnino, Coxe, and more especially our inquisitive and laborious countryman Mr. Tooke; who have all treated not only of the climate, but also of the soil and produce.

It is easily conceivable, that in a country of such vast extent as Russia the climate must be extremely various, and this difference may even be reckoned, in some respects, among its advantages. In several provinces the winter is of long duration, and extremely cold; the short summer is, however, on that account, the hotter. And in these regions, for instance about Kolmogor, Archangel, several districts of Siberia, &c. the alternations of cold and heat are uncommonly rapid and frequent. The agreeable introduction to summer and winter, which we call spring and autumn, is here scarcely known. Amidst the burning heats of summer in these parts, you have frequently to contend with piercing cold. A simple change of the wind is able to produce this sudden alteration. In a place not quite 60° N. lat. it frequently happens that, after a sultry day, towards evening, if the wind veers to the north, such a cold ensues as to render a fur cloak not inconvenient. The formidable severity of the frost makes it necessary to adopt the practice of caulking the windows and covering the outside of the doors of the apartments with a felt made of cow-hair, called by the Russians *voilsk*. To the same extremity of frost it is owing, that, in some parts of Russia, they have no orchard fruits.

In general the governments of Moscow, Nishnei-Novgorod, and Kazan, together with Astrachan, the Ukraine and Livonia, are the most temperate parts of the Russian empire. Upon the whole, the climate of Russia is not unfriendly to health and longevity. Proofs of this may be drawn from the infrequency of diseases among the common people comparatively with other countries, notwithstanding their intemperate manner of life, from the considerable number of aged persons seen in Russia, though there are few physicians, excepting in St. Petersburg and Moscow, which swarm with doctors and surgeons (and where it is remarkable that deaths are earlier), and from the great fertility of the women. The sudden transitions from cold to heat, and *vice versa*, which are occasionally experienced in Russia, are held unwholesome by many; and it must be confessed, that this is true respecting foreigners, yet only for a few years, till they are enured to these changes. For afterwards, strangers as well as natives, in spite of these vicissitudes, generally enjoy a good state of health in those provinces.

The Russian climate has, moreover, even in those regions where it is very rigorous and cold, its peculiar advantages and comforts, among which are the following: the winter, however rude and austere, is in some respects more pleasant than the winter of countries that boast of equable temperature. From the middle of November till April, nay, in some places from September till May, it scarcely ever rains. The roads are, therefore, in winter not so

mirey and the streets not so sloppy as with us. The snow generally falls from November to January, or from August and September to December. Afterwards the sky is almost constantly serene. It is likewise a well-known fact, that in Russia far less hardship is suffered from the cold, than in countries where the climate is incomparably milder: for there proper precautions are taken against the cold, because it is known for certain that it will be intense.

How comes it then, it will be asked, that so many people are in Russia annually frozen to death? That, for instance, in one winter, no fewer than two hundred persons in Moscow alone were found to have thus miserably perished? In a country like Russia, it may indeed unfortunately happen that persons are frozen to death, especially such as have their business out of doors. Such disasters would, however, be very rarely heard of, if the people were more prudent. It is not so much the cold, as the brandy which the labouring class gulp down in such quantities during the winter, that kills so many. From the years 1759 or 1795, no general conclusion can justly be drawn. The winter was then, in several countries, but particularly in Russia, uncommonly severe. In ordinary years, the number of these casualties throughout the empire is not so considerable.

One of the most important benefits of the Russian climate is, that in winter (as we have already hinted) the public ways and roads are in excellent order. The quantity of snow renders them perfectly level and commodious for travelling. No season is, therefore, more studiously chosen for that purpose than the depth of winter; not only for the sake of greater expedition, but many of the highways, being laid with balks or trunks of trees in all other parts of the year, are extremely rough and unpleasant.

Travelling in Russia is performed either with post-horses and *yemshiks*, or with hired horses and *ifvoschiks*. At the post stations only horses are to be had; the carriage must be the traveller's. The expence of posting is trifling, in comparison of what is paid the extra post in Germany. When we travel with hired horses and *ifvoschiks*, it is not necessary to have one's own carriage. We agree with the *ifvoschik* or driver for horses, carriage, and provisions for the whole journey, whether fifty, a hundred, or a thousand versts. This method of travelling is somewhat more tedious than with post-horses, because the same horses being continued throughout, it is necessary to stop at nights; but it is very cheap. Of these *ifvoschiks*, in St. Petersburg alone are at least five thousand. The greater part of them gain their livelihood by letting out carriages and sledges for going about the town. Each of them has a number stamped on a tin-plate at his back, which is renewed or changed every year. For long journeys coaches are rarely used, but either *schlafwagen*s or *kibitkis*. Both are half covered, and made nearly in the same form; only the former are better and more commodious than the latter. In both the passenger lies upon a bed; and they are so constructed, that he can easily change his position either by lying at length or sitting upright. Both may be raised upon either wheels or sledges, as the season requires. Portmanteaus and deep trunks are not suitable to these carriages; but instead of them, flat boxes are placed beneath the bed. *Kozokes*, or sledges entirely close, having a door and a small pane of glass for a window, are likewise not uncommon.

The traveller must provide himself with wine and various other articles of diet for the whole journey; as in all Russia, to the exception of St. Petersburg, Moscow, and a few other towns, no regular inns are found, and nothing is to be had upon the road but bread, milk, which often abounds with taracans (a species of beetle deemed sacred by the vulgar Russians, believing that they procure a blessing

to the house), wretched quas, and still more wretched brandy. The Russian miles or versts are in length about one-seventh of a German mile, or somewhat above three quarters of an English mile. In short, 104½ versts are calculated to make one degree of the equator. A Livonian verst is rather longer than a Russian. In most parts, versts are set up from verst to verst; which though by far not so handsome as the Saxon and Hanoverian mile-stones, yet completely answer the same purpose.

One very beneficial effect of the climate ought not to be omitted, which is, that some animals change their colour in the winter. This is particularly observable with the hares and squirrels; the former turning perfectly white, the latter grey; in Siberia of so dark a grey as to border upon black, in the other parts of Russia only light grey. When the hares, however, are said to become white, it is to be understood of the generality of the common Russian hares, of the *faitzi*, which are somewhat smaller and not quite so well flavoured as the hares of Germany and England. Beyond Moscow, and in some other parts, a larger kind of hares are caught, called *russaki*: these retain their hue. It is certain, that this change of colour in some animals of Russia is owing to the climate, to the severity of the cold. As heat is known to expand bodies, cold must naturally have a contrary effect, and cause contraction. This effect is first and most remarkably perceptible on the surface of bodies, which in animals abounds with hair-tubes. These, on becoming contracted, can admit only the fine aqueous particles, and not the earthy parts of the blood. On this, however, depends the colour. They are white or in general brighter, when but few earthy particles can enter these hair-tubes. Such animals, therefore, as are not very strongly constituted for resisting the cold, must, in intense frost, after shedding their original dark hair, necessarily become whiter. That the squirrels do not, like the Russian hares, turn white, but only grey, is a proof that these animals are stronger than the *faitzi*, and probably proceeds from hence, that the colour of the squirrel is naturally darker, or at least deeper, than that of the Russian hare. It is no objection, that the Siberian squirrel becomes dark grey, bordering upon black. Nothing more can be deduced from thence, than that these creatures are of an incomparably more robust and hardy nature than the Russian squirrels. However dark their hue, it is however not so deep as the red-brown which they put on in summer. The black stripe along the back they retain both in summer and winter. If this explanation of the change of colour in animals be admitted; it must follow of course, that all white animals, including the tame, are weaker than the brown, and this seems warranted by experience; at least wild cattle, which are in general accounted stronger than the tame, are commonly of a darker hue. To conclude; in Russia the *faitzi* and the squirrel in the house change their colour as completely as in the forest, fodder and nourish them how you will.

The greater part of Russia is a flat country, like Poland, of a rich soil, marshy here and there. If we except the great Verchoturian and the Ural chain of mountains, which divide Siberia from the rest of Russia, the ridge which separates Siberia from the country of the Kalmucks and Mongoles, and the Altai between the Irtiseh and Ob, that between the Yenisei and the Baikal, called the Sayane mountains, and the less considerable between the Yenisei and the Lena; we scarcely find in all Russia any elevations that properly deserve the appellation of mountains.

The mountains are distributed by Mr. Tooke into eleven classes, or divisions, of which the greater part consists of principal chains of themselves, whilst others are only continuations

# RUSSIA.

tinuations of huge ridges, extending for the most part into the bordering territories; these divisions are the *Sievernaya-gori*, or northern mountains, extending between the Baltic and the White sea; the *Valday* mountains; the mountains of *Taurida*; the mountains of *Caucasus*; the *Ural* mountains; the *Altay* mountains; the *Sayane* mountains; the *Baikal* mountains; the *Nerebinskaia* mountains; the *Okhotskoy* mountains; and the *Kamishatskoy* mountains; an account of which occurs in appropriate parts of the *Cyclopædia*.

*Forests* rarely occur in some parts of the Russian empire, but in others they abound even to superfluity. Such is the case between St. Petersburg and Moscow, and between Vladimir and Arlamas: also in Siberia, about the Ural mountains, in the district of the river Tara, on the Ufa as far as the Kama, and between the provinces of Perm and Ufa. The forest of Aterkoy is in extent 75 versts.

For an account of the steppes of Russia, see *STEPPE*. The seas forming the boundaries of the Russian empire are the *Frozen*, or Northern ocean, the Eastern or *Pacific* ocean, the *Euxine* or Black sea, the *Baltic* or East sea: and the inland seas and lakes are the *Caspian*, the *Baikal*, the *Ladoga* lake, the lake *Onega*, the lake *Peipus*, and the *Ilmen* lake, the *Bielo-Ozero*, or White lake, the lake *Tshany*, and the lake *Alin-nor*, which see respectively.

The chief navigable rivers that flow into the Baltic, are the *Duna* and the *Neva*; those that fall into the White sea are the *Dvina*, and the *Kuloi* and *Mesén*, both of which flow E. of the Dvina into the White sea, not far from each other, in the district of the town of Mesénk, the former taking its rise in the government of Archangel, and the latter in that of Vologda. The rivers that fall into the Frozen ocean are the *Pesbora*, called also *Bolshaia*, which takes its rise in the western side of the Ural mountains, in the government of Vologda, and following a N.W. course falls into the northern ocean, in the government of Archangel; the *Oby*, the *Irtysh*, the *Tobol*, the *Yenissey*, the *Tunguskis*, the *Khatanga*, the *Lena*, the *Yana*, the *Indigbirka*, and the *Kolina*, which see. The rivers that flow into the Eastern or Pacific ocean are the *Anadyr*, the *Kamishatka*, and the *Amoor* or *Amur*, formed of the *Argoon* and the *Shilka*. The rivers that flow into the Caspian are the *Yemba* or *Emba*, the *Ural*, formerly the *Yaik*, the *Volga*, which takes up the *Kamma* and the *Okka*, and the *Terek*. The rivers that fall into the Euxine are the *Kuban* or ancient *Hypanis*, the *Dou* or *Tanais*, which takes up the *Voronetz*, the *Khoper*, the *Donetz*, and the *Manitsh*, the *Dnieper* or *Borysthenes*, and the *Bogue*. See each respectively. For an account of the canals of Russia, see *CANAL*.

*Population of the Russian Empire.*—In adverting to the *population* and *populousness* of the Russian empire, Mr. Tooke, we observe, properly distinguishes between these two terms; meaning by the former the absolute number of the inhabitants of a country, and by the latter, the relation which this number bears to the surface of ground on which they dwell. By a revision made, or at least completed, in the year 1783, the 41 viceroalties of which Russia at that time consisted, contained of male inhabitants;

Merchants	107,408
Burgbers	293,793
Odnodvortzi and free countrymen	773,656
Exempt from taxes	310,830
Crown boors	4,674,603
Private boors	6,678,239
Total	12,838,529

By doubling the above total, we obtain for the whole number of males and females in the above mentioned viceroalties, an amount of 25,677,000.

In order to obtain the augmented population since the year 1783, we have the following statement:

The total for 1783	25,677,000
The amount of the Cossacks of the Don and Euxine	220,000
Unnumbered tribes and classes at the revision in the year 1783	1,500,000
Total for 1783	27,397,000
Annual increase of 250,000 in 12 years	3,000,000
New acquisitions since 1783, or the nine viceroalties of Taurida, Minsk, Brazlau, Vofnesensk, Podolia, Volhynia, Courland, Vilna, and Slonim	5,755,000
Grand Total	36,152,000

Whence, by the most moderate estimate, the whole population of the Russian empire may be stated for the year 1795, in round numbers, at 36,000,000.

Of this mass of population, the greatest part belongs to European Russia. The five governments of Perm, Ufa, Kolyvan, Tobolsk, and Irkutsk, comprehended under the general name of Siberia, contain, according to the revision-lists, only 2,215,000, and allowing for the unnumbered classes and tribes, perhaps above  $3\frac{1}{2}$  millions of inhabitants. Hence it appears, that the population of the European part is about fourteen times greater; and the Russian empire, which, with regard to superficial contents, mostly belongs to Asia, must in respect of population be reckoned as belonging to Europe. The population of the different governments is very various; the most populous being that of Moscow, which contains upwards of 1,139,000 persons, and the least populous is that of Taurida, the inhabitants of which are computed at about 150,000.

But although the Russian empire ranks high in *population*, with respect to *populousness* its place is very subordinate. European Russia has a population of 405, and Asiatic Russia of 11 persons to a square mile: and if we compare the governments with one another, the result will be, that of 45 (the five newly acquired not being reckoned), eight contain below 100; nine contain from 100 to 500; seventeen from 500 to 1000; seven from 1000 to 1500; three from 1500 to 2000; and only one above 2000, inhabitants, on a square mile. This last honourable precedence is held by the government of Moscow, which (including the metropolis) numbers 2403 persons on the forecast superficies. To the second class belong the governments of Kaluga, Tula, and Tchernigof: and to the third, Riazan, Kursk, Kief, Orel, Kharkof, Yaroslaf, and Novgorod Sieversk. The sixth and poorest class comprises, with the countries of the Cossacks, the north European and Siberian deserts, where the degree of population is so low, that the government of Tobolsk has but seven, and that of Irkutsk only three persons in every square geographical mile. In these countries, however, the unregistered tribes are the most numerous. The most populous district of the Russian empire lies between the 49th and 58th degrees of N. lat.; and further both to the N. and S., as well as E. beyond the 65th degree of longitude, this populousness is continually decreasing. From a table of birth, deaths, and marriages in 1799, extracted by Mr. Tooke from a German publication, we may deduce the following conclusions. The overplus of

## RUSSIA.

births, unparalleled in the annals of political economy, forms a characteristic feature of the Russian empire; and shews, that if the same increase of population should proceed for 10 years, the number of Russian subjects will be augmented by 5,000,000. It also appears, that upwards of 23 boys were born to 20 girls, whereas 104 persons only of the former died to 100 of the latter; and this favourable proportion of the males to the females indicates the military grandeur to which the Russian empire is capable of attaining; unimpeded by such wasteful wars as that which has recently occurred. Moreover, it appears that the mortality in common years throughout all the Russian dominions is as 1 to 58; whence it may be calculated, that the number of Russian subjects of the Greek church would amount, exclusively of the inhabitants of the eparchy of Bruzlaw, to 31,339,620 souls. Adding to this number the inhabitants of the new possessions in Poland, which in 1795 contained 4,592,544 persons, and about 5,000,000 of Russian subjects of various Christian sects, and of the Jewish, Laman, and Schaman professions, the whole population of the Russian empire will appear to amount to upwards of 40,000,000 of souls.

*Progress of Population in Russia.*—The first census, namely that in 1722, gave 5,794,928 males; which, admitting an equal number of women, makes a population of 11,589,856 individuals. How much ought we to add for the new acquisitions, in which the census, or revision, as it is termed in Russia, did not take place?

According to Mr. Hermann, in his *Statistic Journal*, vol. i. part 2. p. 54, an enumeration made in Little Russia, in 1768, gave 955,228 inhabitants; another made in Finland, in 1755, gave 117,998; Esthonia, in 1773, had 176,000; Livonia, 447,360. All these make a sum total of 1,696,586 persons. These enumerations, however, being made 20, 30, 50 years after the first revision, it is possible that the population may have increased or diminished during the interval. If we compare these data with the enumeration made in 1805, we shall find that Finland, in 49 years, has gained 64,392 inhabitants; Esthonia, in 31 years, 36,948; and Livonia, 138,097: making a sum total of 239,437. The population in the provinces bordering the Baltic, then, has gained about one-fourth during the latter half of the 18th century. On comparing the population of Little Russia, as above stated, with that of the governments of Tchernigof and Pultava, a surplus will be found, in 1804, of 1,465,465 individuals above the enumeration of 1768. According to this statement, the population has more than doubled during the last 50 years. This result corresponds very well with the observations made on the registers of births and deaths, that the progress of population is very slow in the Baltic provinces, and very rapid in Little Russia. It has gained of late, especially by the commerce of Odesa; the price of land has risen considerably, and the fertile steppes have likewise been cultivated.

Admitting the like proportion in the progress of population in these provinces, during the former half of the 18th century, which is certainly a great admission, we must deduct from the above stated population of the Baltic provinces one-fourth, and there will remain 555,979; and one half of the population of Little Russia in 1768, leaving 477,614. Agreeably to this statement, the population of all the provinces acquired posterior to 1722, may be estimated at 1,033,533.

It remains now to compute what may have been the number of free persons not included in the revision. Seeing that, at the last revision of 1796, there were 16,000,000 of males included in the list of those who paid the regular

obrok, for 1,000,000 that did not pay that tax, we may compute, that at the first revision, in which the number of revisionaries was 5,000,000, there were 300,000 male freemen, composing, together with their wives, the sum of 600,000.

In conformity with these calculations, the probable population of Russia, in 1722, will be,

Revisionaries - - -	11,589,859
Free individuals - - -	600,000
Conquered provinces - - -	1,033,533
	13,223,392

Le Clerc, in his *Essay on the Population of Russia*, published in 1777, states it at 14,000,000; Benedict Francis John Hermann, at the same; which is probably accurate. But when Voltaire reckons the population during the last years of Peter the Great at 18,000,000, he confounds a later period with the era of that monarch. It appears to me, adds Mr. C. T. Hermann, that 14,000,000 would be the most probable amount, if we consider the imperfection inseparable from a first census, and the uncertainty of the calculations respecting the newly conquered provinces.

The second revision, in 1742, gives 6,673,167 males; and, supposing a like number of females, we have 13,346,334 for the inhabitants of Russia at that time. To this must be added the conquered provinces, and the free individuals. As we subtracted a fourth from the population of the Baltic provinces in 1722, the deduction of one-eighth will suffice for their population in 1742; the remainder is 648,689; and, subtracting a quarter from the population of Little Russia in 1768, there remains 706,421; making a total of 1,355,110 for the population of the conquered provinces. The number of revisionaries having augmented by 1,000,000 since 1722, we must increase the number of freemen at least by 50,000, considering the progress of industry, and the better regulations adopted by government. The population, therefore, in 1742, will be,

Revisionaries - - -	13,346,334
Free individuals - - -	700,000
Conquered provinces - - -	1,335,110
	15,381,444

Hermann admits for 1742 the round number of 16,000,000. This is a very probable estimate, as the enumerations in Russia are always below the mark.

The third revision, in 1762, gives 7,363,548 males, which supposes a total of 14,727,096 individuals; and, by the proper ratio, we take the population of the conquered provinces at 1,696,586. The revisionaries being nearly one half what they are at present, we may compute the same to hold with the freemen, which would make their number 400,000. The probable population, therefore, of 1762 is as follows:

Revisionaries - - -	14,727,096
Free individuals - - -	300,000
Conquered provinces - - -	1,696,586
	16,723,682

Marshal in 1768 and 1770, and Williams also in 1768, admit 18,000,000; l'Evêque in 1782, and le Clerc in 1783, 19,000,000; Schlätzer and Busching, in 1765, 20,000,000;

# RUSSIA.

20,000,000; and Mr. C. T. Hermann is of this last opinion. The real number, in 1762, apparently lies somewhere between 18 and 19,000,000.

The fourth general revision, in 1782, gives 12,838,529, and, with the females, 25,677,058; or, according to Hermann, 26,358,822. The two capital cities, the military and the nomadic tribes, are not included in this calculation. These at present amount to 2,960,000: at that time we may suppose them to have amounted to 2,000,000. By this statement, the population of Russia, in 1782, would have been between 27 and 28,000,000. Crome, in 1785, admits 23,000,000; Sufmilch, 24,000,000; Plefchtſcheef (not reckoning the clergy, the civil establishment, the military, and the Nomades) admits 26,617,698 in 43 governments; while Hupel in 1780 to 1790, and Hermann, compute 28,000,000.

The fifth revision, in 1796, gave 17,816,370 males, which, supposing an equal number of females, makes the population amount to 35,632,740; or, according to the datum 16,223,229, (which we consider greatly below the truth,) 34,038,599. If we add the two capitals, the military, and the Nomades, computing them at 2,960,000, the population in 1796 will amount to 36,998,599. Busching and Beaufobre make it 30,000,000; Schlätzer, 33,000,000; Hermann, 33,250,000; Meufel between 35 and 36,000,000; and Storck, 36,000,000.

Following these data, the progress of population in Russia, brought on partly by the improvement of the interior, partly by new acquisitions, has been as follows:

In 1722	-	14,000,000.
1742	-	16,000,000, after 20 years.
1762	-	19,000,000, after 20 years.
1782	-	28,000,000, after 20 years.
1796	-	36,000,000, after 14 years.
1806	-	41,000,000, after 10 years.

This astonishing increment has preceded in a great measure from new acquisitions. It would prove highly interesting, were we able to ascertain nearly the progress of the Russian population, independent of the recent acquisitions.

We shall admit for Little Russia and the Baltic provinces the number exhibited by the enumerations of 1755, 1768, and 1772, which yields a total of 1,696,586; sub-joining the new acquisitions since 1773, according to the data published by general Oppermann on his map of 1796, constructed by order of government, for delineating the new limits. According to this author, Russia acquired,

	Individuals.
By the first dismemberment of Poland in 1773	1,226,966
By the peace with the Ottoman Porte in 1774	} 171,610
and 1783	
By the peace with the same power in 1791	42,708
By the second partition of Poland in 1793	3,745,663
By the annexation of Courland	387,922
By the subsequent partition of Poland in 1795	1,407,402
Total of the acquisitions since 1773	6,982,271
Adding the Baltic provinces and Little Russia,	} 8,678,357
we get	

Here we have the total amount of the population of the countries conquered, down to 1795.

All this, however, was obtained by means of first enumerations, which were of course incorrect. Those made

down to 1804 ought to be more accurate. The administration must have acquired considerable influence, especially after the organization of the governments in 1775. It will be of importance, therefore, to know the effect of these causes, as exhibited by the last census, in 1804, which Mr. Hermann delivers to us in the following tables.

Little Russia comprehends the governments of Kief, Tchernigof, Pultava, Ukrainkoi-slobode, with a part of Ekaterinoslaf and Kursk; to which must be added the country of the Donkoi Cossacks, as peopled by the inhabitants of Little Russia. The whole of this vast territory, called the Ukraine, formed the boundary between the Turks and Tartars. Its population, in 1804, was as follows:

	Males.	Females.
Kief - - -	574,217	538,404
Tchernigof - - -	534,712	538,570
Pultava - - -	713,772	732,639
Ukrainkoi-slobode - - -	420,304	418,781
Ekaterinoslaf - - -	210,815	183,363
Cossacks of the Don	161,100	194,521
	2,614,920	2,606,278

The Swedish provinces are a part of Karelia and Ingria, constituting at present the governments of St. Petersburg, Finland, Esthonia, and Livonia. Their population, in 1804, was as follows:

	Males.	Females.
St. Petersburg - - -	268,748	270,920
Finland - - -	94,397	87,393
Esthonia - - -	107,357	105,591
Livonia - - -	290,014	295,443
	760,516	759,947

So that the number of individuals in the Swedish provinces and in Little Russia is 6,741,661.

On comparing this number with the preceding enumerations, it will be seen that the Swedish provinces have gained one-fourth, and that Little Russia has nearly doubled; since it is certain that, in this last census, the several provinces belonging to Little Russia in its largest extent have not been included.

The Polish provinces annexed from 1773 to 1795, including Courland, are White Russia, Lithuania, and the Polish Ukraine, or the governments of Minsk, Vitepsk and Mohilef, Grodno and Vilna, Podolia and Volhynia. The state of their population, in 1784, was as under:

	Males.	Females.
Minsk - - -	431,586	426,940
Vitepsk - - -	343,716	330,624
Mohilef - - -	403,614	397,381
Grodno - - -	300,278	290,782
Vilna - - -	465,224	460,046
Podolia - - -	379,215	556,870
Volhynia - - -	564,586	522,182
Courland - - -	191,910	189,366
	3,080,129	3,174,191

According to general Oppermann, the population of these provinces, in 1796, amounted to 6,767,953; whence it appears that the population of Poland is stationary.

The Turkish provinces are Cherson, Taurida, the country of the Cossacks of the Euxine, and the residue of Ekate-

# RUSSIA.

Ekaterinoflaf, to which may be added Caucasia. The population of these provinces is,

	Males.	Females.
Cherfon - -	145,814	124,321
Taurida - -	102,826	88,864
Cossacks of the Euxine	20,240	9,155
Caucasia - -	34,849	29,240
	303,729	251,580

As the Cossacks of the Euxine have very few women, and still retain many customs derived from their ancestors, the famous Zaporogian Cossacks, so called from *za, trans*, beyond, and *paragi*, cataracts, (the Cossacks beyond the cataracts,) the foregoing statement is probably correct. We learn from general Oppermann, that in the Turkish provinces conquered in 1774, 1783, and 1791, there were 214,318 individuals of both sexes. This small population, in a tract of country so immense, has increased undoubtedly, in consequence of a more regular administration; but not so much as would at first sight appear, because we must strike off the Cossacks of the Euxine, Caucasia, and the Russian and foreign colonies domiciliated in these regions. Besides, if we consider the incompleteness of a first enumeration, it is but reasonable to suppose that general Oppermann's estimate is too small.

Thus it appears that the population of the territories acquired since 1773 was, in 1804,

Little Russia - - -	5,221,198
Swedish provinces - - -	1,520,463
Polish provinces - - -	6,454,320
Turkish provinces - - -	555,309
	13,751,290

According to the data above noticed, we are to subtract from the aggregate population of Russia, for the provinces acquired,

From 14,000,000 in 1722		
1,033,533	-	12,966,467
From 16,000,000 in 1742		
1,355,110	-	14,644,890
From 19,000,000 in 1762		
1,696,586	-	17,303,414
From 28,000,000 in 1782		
8,678,857	-	19,321,143
From 36,000,000 in 1796		
13,751,290	-	22,248,710
From 41,000,000 in 1806		
13,751,290	-	27,248,710

The last column gives us the rate at which the population of Russia proper has increased.

Whence it follows, that the population of Russia, exclusive of the conquests since the reign of Peter I., gained in 20 years, between 1722 and 1742, 1,678,423, or 83,921 annually. In the 20 years between 1742 and 1762, 2,658,524, or 132,926 annually; that is to say, 49,005 more annually than during the first period. In the 20 years between 1762 and 1782, 1,676,253, or 83,812 annually;

less by 49,114 than during the second period. In the 14 years between 1782 and 1796, 2,927,567, or 146,378 annually; more by 62,566 than during the preceding period. In the 10 years between 1796 and 1806, 5,000,000, or 200,000 annually; more by 53,622 than during the antecedent period.

By the above table, it is obvious that the population of Old Russia has more than doubled, or that it is at present to what it was in 1722, as 2½ to 1. It is apparent also that the progress of population has not been uniform, that it has had accelerations and retardations, that the most favourable periods were during the reign of the empress Elizabeth, between 1741 and 1761, and the years of the peace of Catharine II. between 1782 and 1796. The population still advances in the later periods, but the rate is slower. What may be the cause of these phenomena?

The population of Russia has more than doubled during the last century, though Smith supposes that the population in civilized countries only doubles once in 500 years. It has doubled in consequence of a better regulated administration; of the security the government has afforded to the nation; of the capitals belonging to foreigners placed in the country, and which for a long time constituted the soul of the inland commerce; in consequence of the progress of national industry, which was the result; of the increase of knowledge, by new commercial connections with other countries of Europe, and by the means of instruction furnished by government to the other inhabitants of Russia; and, finally, in consequence of the removal of several obstacles which checked the progress of industry, as the abolition of the custom-houses of the interior, under the reigns of the empress Elizabeth and Catharine II., the improvement of the roads, and the multiplication of canals.

What a dismal picture does Russia present to us in the fifteenth, sixteenth, and seventeenth centuries! Jofafa Barbaro, in 1436, reports, that from Moscow to the frontiers of Poland, the whole country was one vast desert; the villages, burnt and abandoned, offered no other accommodation to strangers than a place to kindle a fire. Conzarini confirms this statement in 1483. Meyerberg, in 1661, found between Viasma and Mosaik, a distance of 130 versts, only a single village. The road between Smolensk and Moscow was dangerous, according to Lybeck, in 1675, on account of the wolves that attacked travellers. Ulfeldt, the Danish ambassador, in 1525, found the country between Moscow, Novgorod, and Pskov, laid entirely waste by the intestine wars under Ivan Vasilievitch II. Poffevin, in 1581 and 1582, travelled whole days in the interior of Russia without meeting a single individual. The whole country between Kazan and Aitrachan was a continued desert. Even the cities had greatly suffered. Poffevin estimates the population of Moscow at 30,000; that of Novgorod was diminished by the plague to 3000; and Kief, in the time of Herberstein, in 1516, was almost in ruins. Besides the devastations committed by the domestic feuds and foreign invaders, the number of impost, and the severity of the commissioners who levied them, depopulated the northern provinces which had not suffered from those disasters. We learn from Fletcher, that in the year 1588, 50 villages were abandoned between Vologda and Yaroslaf. At Ustjug bread was almost unknown, and the same destitution of that article of life was felt on the Dvina in the time of Herberstein. Famine and pestilence often committed their ravages among the melancholy remnants of this unfortunate population, as in 1525, in 1601, and in 1615. M. Meiner informs us, that the city of Novgorod lost in one winter no fewer than 18,000 individuals, constituting nearly the whole of its population.

It is neither to the mildness of the climate, nor to the fertility of the soil, that we are to ascribe the rapid increase of population during the eighteenth century; but to a better organized administration, and the security which resulted from it. An infant state, supposing it tolerably well governed, and connected with countries long civilized, ought to make prodigious progress in improvement and population.

That period of the reign of Catharine II., in which she took in hand the amelioration of the several governments, was particularly propitious to the progress of population. The organization of the governments in 1775 was the great political scheme that procured the subjects a greater degree of security and happiness. The ukase of 1782, respecting the liberty of working the mines, the establishment of normal schools in 1783, the rights granted to the nobility in 1785, the improvement of the high roads in 1786, and especially the erection of the bank in the same year, were all calculated to promote the happiness of the subject, as far as it depended on the government. The bank, from its very commencement, had a surprising effect upon the progress of agriculture. That patriotic sovereign removed several obstacles to the prosperity of her subjects, such as the want of liberty to be industrious, the want of communications, the want of knowledge, and of a medium of circulation.

The population of Russia has more than doubled during the eighteenth century. Have we reason to expect the same progress during the nineteenth?

If we consider only the extent of the surface capable of cultivation, which is computed at 80,000,000 of square miles, we must conclude that Russia is capable of supporting 960,000,000 of inhabitants, or almost as many as at present exist on the earth. If we consider the surplus of births as a total gain to the population, this surplus, amounting at least to 500,000 annually, would in 32 years amount to 60,000,000, in 56, to 80,000,000, &c.

Experience, however, shews us that the progress of population does not depend solely upon the extent of soil capable of cultivation. There are spots left uncultivated in the countries where agriculture has made the greatest advances, even in England, Flanders, and Lombardy. This progress depends still less on the surplus of births. Every where the number of births exceeds that of deaths. The population is always proportionate to the state of national wealth. The most decisive proof, therefore, of the prosperity of a country, is the increase of the number of its inhabitants. In Russia the population has more than doubled in 34 years. Whence we may infer, that its agriculture, the principal branch of its industry, has also doubled. The increase of Russian commerce depends upon peace, and upon the augmentation of knowledge. On these accounts we cannot expect so rapid an increase of national riches, and consequently of population, during the nineteenth century as obtained during the eighteenth.

Experience has demonstrated the accuracy of this mode of reasoning. The progress of the population has become slower since the fifth revision. The annual surplus of 60,000 has been reduced to 50,000 during the last ten years.

To establish this fact, M. Hermann has compared the statements respecting the population of the governments of Moscow, Tula, Kaluga, Yaroslaf, Orel, Kursk, Vladimir, Riazan, Penza, Kazan, Tver, Smolensk, Tambow, Nijegorod, Pskove, Voronetch, Simbirsk, Kostroma, Viatka, Novgorod, Saratof, Perm, Orenburg, Vologda, Olonetz. The statements respecting the population of these 25 governments, according to the fourth revision of 1782, gives

9,939,790, males; that of the fifth revision of 1796, fourteen years after, 10,223,672; that of the enumeration of 1804, eight years after, 9,989,531. So that the population gained during the first period 867,873, and during the second period lost 239,141. In the first period there are only three governments whose population has diminished; viz. Kaluga, Kostroma, and Voronetch. All the others had increased. But during the second period Moscow alone gained considerably, namely, 100,000 males; Voronetch, which had lost before, gained 150,000 males; and Viatka gained 37,000. Kursk and Orel have gained a few thousands; Tula, Yaroslaf, and Perm, some hundreds. The other seventeen governments have lost, and several of them considerably. In like manner, Tambow has lost 88,000 men, Nijegorod 55,000, and Simbirsk 110,000 men in eight years!

It is worthy of observation, that those governments which have been long in a high state of cultivation, as Tula, Yaroslaf, Kaluga, Tver, Pskove, Kostroma, Smolensk, Vladimir, have neither lost nor gained much. The population, and of course the industry, is stationary. The governments less improved, as Viatka and Voronetch, have gained conspicuously; whereas the governments richest in corn, as Tambow, Nijegorod, Simbirsk, have lost the most.

The rapid progress of population between the fourth and fifth revisions is the natural effect of the sensible advances made by agriculture, in consequence of the many recent beneficial institutions, and especially the establishment of the bank. These institutions and new funds have already produced their effect. At present, the ancient sources of national wealth flow less abundantly, and it is not easy to open new ones. It may be presumed then, that the population of Russia will remain a long time between 41,000,000 and 43,000,000. Unforeseen circumstances, however, may give a considerable population to the south of Russia. For instance, the astonishing commerce of grain at Odessa, between 1800 and 1805, increased the value of all the lands as far as Kief, and even the fertile steppes were brought into cultivation. Labourers were wanting; and even half the produce was offered to those who would gather in the other half. The commerce of Taganrok likewise furnishes ground for hope: and agriculture appears to be making some progress among the nomadic tribes.

A country is sufficiently peopled when the generality of the inhabitants are in easy circumstances. Such a population alone is desirable, and useful to government. A country is not sufficiently peopled when the demand for labourers, and the means of maintaining them, are excessive, as in some of the southern provinces of Russia. A country suffers from its population, when the thousands of rich are obliged to maintain the millions of poor. Such a fallacious population must either perish, or emigrate, or occasion revolutions.

The nations inhabiting the Russian empire are; Russians, Cossacks, of whom are four denominations, Samoyedes, Morduanes, Cheremisles, Chuvashes, Votiaks, Vogules, Permiaks, Sirianes, Olliaks, Barabinses, Tunguses, divided into the Connei Tungusi, Olenni Tungusi, and Sabatshi Tungusi, thus discriminated because some Tunguses travel with horses, some with rein-deer, and others with large dogs, Kalmucks, Burats, Yakutes, Yukagiri, Korzaki, Kamtschadales, Tartars, who are likewise divided into several kinds, Finns, Elthionians, Lettes, Livonians, Armenians, Indians, besides the Germans and other Europeans. To these might be added the Chuktshi, Thalatshi, the Kurilli, and perhaps yet others. These different tribes and populations are of as various manners, tempers, and habits of life: to specify them distinctly would engage us in too wide a field

of description. But of the principal nation, the Russians, it will be expected of us to make some observations.

*Characteristics, &c. of the Inhabitants of Russia.*—The Russians are described as a moderate-sized, vigorous, and durable race of men. Their growth and longevity, however, are different in different districts; but upon the whole they are rather large than small, commonly well-built, and very seldom deformed. Their common or discriminating features are, a small mouth, thin lips, white teeth, little eyes, low forehead, and nose often small and turned upwards; the beard almost always very bushy, and the hair varying from dark-brown to red; but seldom quite black. Their countenance expresses gravity and good nature or sagacity. Their senses of sight and hearing are very acute, and the gait or gestures of the body indicate a peculiar and often impassioned vivacity. As to the females, a delicate skin and ruddy complexion are in the vulgar opinion regarded as the first requisites of beauty. Young girls arrive at maturity in the 12th or 13th year, and this is ascribed to the frequent use of hot baths; but on the same account married women seldom retain the fresh complexion and the peculiar charms of youth beyond the first lying-in.

The character of the Russians is mixed, like that of most other nations, as well as of individuals; the Russian character is, however, composed of a very extraordinary mixture. The Russians are a people who, with a particular degree of pride, combine much submissiveness, levity, kindness, especially towards foreigners, prudence and cunning on one hand, but likewise fidelity and honesty on the other, a certain propensity to superstition and usury, and a great proportion of selfishness. The Russian easily runs from one extreme to the other. Prone as he is to superstition, so apt is he to be carried into the contrary failing. He hesitates long before he engages in friendship; but being then generally firm in his attachment, he is revengeful when, in spite of his caution, he is deceived in the choice of his friend: while he scolds, threatens, and rages, no harm is to be apprehended; but if he makes no noise when he thinks himself offended, he is a dangerous enemy. He is greatly swayed by self-interest, and surrenders himself entirely to the impetuosity of his passions. Gaming and drinking have an irresistible authority over him. Among the lower sort it is generally the men who give themselves up to these excesses; though, indeed, a drunken woman staggering along the streets is no uncommon sight. The Russians are remarkable for their comeliness of person, strength of body, courage and intrepidity in war, ingenuity, wit, and obedience to the commands of their superiors.

The insatiable greediness of the common people for spiritous liquors, especially in the *maslanitza*, or carnival season, is in a great measure ascribable to the rigorous fasts of the church, and the slender diet they live upon throughout the year. Their food chiefly consists of turnips, cabbages, pease, salt-cucumbers, onions, coarse fish, with oil and black bread. Their common beverage is quas, which is a kind of acidulated small beer.

The Russian women are excessively fond of paint, and look upon ruddy cheeks as the very essence of beauty; so that in the Russian language, red and beautiful are convertible terms. Even the village girls all over the country know how to prepare a particular herb to the purposes of rouge.

Persons of distinction dress after the German and French fashion, and are passionately addicted to state and splendour. The dress of the common people is coarse and simple, but they are neat and cleanly in their apparel. Both sexes wear a crucifix on their breasts, suspended round the neck by a

string, which is put on at their baptism, and never afterwards put off; those of the peasants are of lead; but the better sort have them of silver or gold. The peasants let their beards grow to their full length. In Russia there are few peculiar diseases. The common Russians use but few medicines, their place being supplied by the sweating-bath; and indeed baths have been common in this country from time immemorial. In the bath-room the heat is usually from 32° to 40° of Reaumur; and by throwing water every five minutes on the glowing hot stones in the chamber of the oven the heat rises to 44°. The vapour-bath is habitually used by the Russians once or twice a week; for which purpose almost every house has the necessary apartment. They often walk forth naked from the bath, run about in the cold, and roll themselves in the snow, or in summer plunge into the water, and then rush again into the bath.

A particular air of grace and civility is observable in the salutations even of the common people to one another; but on entering a room, before they greet the company, the custom is to make repeatedly the sign of the cross, at the same time bowing as often to the picture of some saint, which is so placed in every room as to be seen immediately on coming in. In visits of ceremony, it is usual for both men and women to welcome each other with a kiss. Great deference, approaching to servility, is shewn to persons of superior rank.

The nation consists chiefly of the nobility and peasantry, to which we may add the burghesses and the Kozaks or Cossacks. The nobility formerly consisted solely of knæses or princes. Boyar is not a title of nobility, but anciently denoted the possessor of a post or office, as a privy counsellor, &c. To the former, Peter the Great added the titles of count and baron. The knæses are extremely numerous, and, therefore, unless very rich, or of illustrious races, not greatly honoured. This great multitude of knæses proceeded, among other causes, from the custom of giving that title to the baptized Tartarian murzas, in the idea that murza, among the Tartars, was of nearly the same import as knæses. Every knæses, as well as every count, even though no more than a common soldier, has, in virtue of his birth, the style of *vashe sietstvo*, which is commonly translated *your excellency*. The nobles may be proprietors of land and people, and hold the highest offices in the civil and military departments. The “Dvorianini” are a kind of city-nobles, and the “Odnodvortzoi” are the lowest class of noblesse. The burgher state, yeomanry, or commonalty, is composed of the “Pofatski” and “Rafnotshintzi,” who live in towns and villages, governed by their proper magistrates, whether as merchants or tradesmen. They are excluded from offices and posts of service of honour, and furnish head-money and recruits, but cannot be vassals. The peasants are vassals of the great, attached to the soil, *glebe adscripti*, and groan under many oppressions: far, however, from being dull and stupid, they are remarkably ready witted, and are in no want of natural parts. Of the peasantry, such as belong to the crown and the monasteries pay taxes according to the laws of the land, and are liable to other duties imposed by the same authority; but they may be transferred as donatives from the crown. They may pursue trade, in connection with their rural concerns, if they think it beneficial or convenient. Noble boors are the vassals of their lord; from these recruits for the army are taken by lot. Cossacks form a particular class originating from the peasantry; they live exempt from taxes in villages, forts, and petty towns, on the produce of their fields and pastures, or the labour of their hands; they furnish no recruits, and are not given away as serfs, and they enjoy other privileges. But they all serve as light-horsemen, as early and as long

as they are fit for it, providing themselves with horses, clothes, and accoutrements, and only receive pay when they are in actual service. See *COSSACKS*.

The intercourse between the sexes is more free than in other countries, which is owing to the contracted space of their habitations and sleeping rooms, their baths, the simplicity of their conversation, and their artless songs. The behaviour of husbands towards their wives is, in comparison with that of more polished nations, rough and austere. The marriage contract is made with mercantile punctuality; the betrothing is performed with ecclesiastical rites, generally eight days previous to the marriage, and is indissoluble. The marriage is solemnized in the church before the altar, to which they proceed with the figure of some saint carried before them; and during the ceremony a crown is put on each of the heads of the married pair. The priest, with due forms, changes their rings, admonishes them of their reciprocal duties, gives them a cup to drink, in token of the union of their fortunes, and dismisses them with his blessing.

The national diversions of the Russians on holidays, at weddings, and on other occasions of festivity, are very various, and much resemble those that are customary with the Persians, Arabians, and Egyptians. Their music is more usually vocal than instrumental. Their songs are simple recitations, ancient or modern, on the subjects of love, nature, and tales of chivalry, giants, and heroes, frequently lewd; and their melodies are uniform and monotonous, but sometimes sufficiently pleasing. The little groups of girls, sitting together in an evening and singing, afford much amusement. The most complete vocal music is that which is heard in their churches, on Sundays and holidays; which, as the church allows of no instrumental music in divine worship, is performed by singers expressly taught and mostly brought from the Ukraine. The substance is Slavonian poetry; the notes are expressed by points, after the very old fashion, for four voices. The present choral music is mostly by mottete. The most common instrument of the nation is the Cow-horn, which is a kind of cornet, of from one to four feet in length, made of wood or tree-bark. For a description of the balalaika, see *BALALAIKA*. The gudak is a miserable violin with three strings; the dutka consists of two parallel reed-pipes, each with three holes, differing in their notes up to an octave, so that the hearer conceives that two are played on it. The riek is a common village lyre; and the valinka a diminutive pair of bagpipes. The gusli is a horizontal harp with wires, played on with the fingers, and capable of any kind of music: it is a pleasing instrument and much used; and so is likewise the cornet among sailors and boatmen: the sailors also make a kind of jingling noise with two bunches of little bells, keeping time with their music. Dancing is a diversion to which the Russians are very much devoted; and they are usually attached to gymnastic pastimes.

The dead are long and sincerely lamented by their surviving relations; but, from a natural repugnance to the idea of death, they use little ceremony with the corpse. They bring it to the grave in an open coffin, covered only with a pall, attended by priests, chanting hymns, and bearing cresses and lighted tapers in their hands. At the place of interment they take leave of the body by a kiss, then fasten up the coffin, and let it down into the grave. Persons of the lower class bury their dead in their ordinary clothes. At the new year is annually held a feast of the dead, on which occasion every body visits the grave of his relations, lays some victuals upon it, and hears mass, in payment for which the priests get the victuals.

The ancient orthodox Greek religion is universally ac-

knowledged both in doctrine and discipline. (See *Greek Church*.) The churches and sacerdotal vestments are very magnificent. The people are strict in the observance of the outward forms of religion; attendance on mass, keeping the fasts (which take up one-third of the year), performance of domestic devotions, confession, receiving the sacrament, &c. Passion week is observed with great apparent solemnity; but Easter week is passed much as in other countries, in various diversions, drunkenness, and debauchery. The Russians are superstitious, both in their notions and practices, believing in ghosts, apparitions, and hobgoblins. Some specimens of their superstitions we shall here subjoin. On the Thursday before Whitsuntide, the girls celebrate the festival of the Slavonian goddess Lada and her son Dida, with singing, dancing, and decorating a birch-bush with garlands of ribbons; which they afterwards throw with much solemnity into a river, and infer, from the figures assumed by the ribbons in the current, to whom they shall be married, and their subsequent condition. On the fifth of January they go by night into a cross-street, or into a cellar, which is called "To go hearing," and fancy they hear, in every sound, the prediction of their destiny. The day after Christmas is solemnized by the midwives, because the Virgin Mary's midwife had a great hand in the redemption of the world: but it is needless to enlarge in this way.

The clergy in Russia enjoy peculiar privileges: they cannot suffer corporal punishment without being previously defecrated, and they are exempt from taxes. The empire comprehends, according to the usual enumeration, 18,350 parish churches and cathedrals of the orthodox Greek religion. The number of Russian clergy is computed at 67,900 persons, without including their families. Some authors assert, that the whole empire contains 480 monasteries and 74 nunneries; the former including 7300 monks and the latter 5300 nuns; but these numbers are supposed to be exaggerated: Mr. Coxe states the nuns at only 1300, and this is said to be a just estimate. The monasteries all follow the rule of St. Basil. By the laws of Russia no ecclesiastic can be brought before a temporal judge, unless commissaries of the clerical order be likewise on the bench. For the boors of Russia, see *Boors*.

Throughout the old provinces of Russia not any beggars are to be seen. The inferior class of nobility, which is the most numerous, live at their ease in the country. They are the true Russian farmers: their well-being depends on the progress of agriculture, and it prospers in their hands. The peasantry are very far from being unhappy. They are in general much more at their ease than the same order of men were in France, under the ancient government, when it was hardly possible for a carriage to stop, any where between Lyons and Paris for example, without being surrounded by a clamorous troop of beggars. Even the number of wealthy peasants is by no means inconsiderable; and it must every day become greater, so long as they retain their ancient simplicity of manners. Their savings necessarily accumulate under the form of capitals, and these capitals by degrees become productive; for many peasants have already abandoned agriculture, to engage in other branches of industry, as manufactures and trades, and even commerce. It is only in Finland and the Polish provinces that the peasants are poor.

The power of a state does not solely depend on the number of its inhabitants, but upon their wealth and activity. Russia, in this respect, has no reason to complain. She is sufficiently peopled for the actual state of her national riches. What would not this empire become, if its population was more concentrated!

The Russian language is an improved dialect of the Slavonian, which, with its characters, is still used in the offices of religion. According to M. Schlötzer, it is preferable to almost all the European languages. It is rich in words, soft, expressive, and requires great flexibility in the organs of utterance. It is, however, difficult of attainment by foreigners, on account of its innumerable peculiarities and anomalies. The Russian grammarians themselves are not agreed even concerning the number of letters contained in the alphabet. Some make it to be forty-one, and others thirty-one; whilst Rodde, with greater propriety in the opinion of Mr. Tooke, fixes the number at thirty-eight. Some of these letters are merely notes of accent in pronunciation.

*Government of the Russian Empire.*—As far as history reaches, Russia has always been an hereditary empire. The throne was occupied by Rurik and his descendants, according to the usual computation, from about the year 862 to 1598: and when Michael Feodor Romanow ascended the throne in 1613, a charter was executed confirming it to him and all his posterity, by which act Russia was in a formal manner declared a real hereditary empire. His accession to the throne was by unanimous election, “in a general assembly of the boyars and the other estates of the country,” and partly by his relationship to the tzarian family now extinct in the male lineage, and also in virtue of nomination, by which his father had already been heir to the throne. On a vacancy the heir takes possession of the throne, without any invitation or acts of homage. The oath of allegiance is usually administered to all classes of subjects, though the sovereign may dispense with it. The coronation has for many centuries been customary in Russia, and is still continued, on which occasion the sovereign, who puts the crown on himself, is anointed with holy oil. Since the introduction of Christianity, the sovereigns have always professed themselves of the orthodox Greek church. As to the title of the sovereign, we may observe, that Ivan Vassilievitch declared himself tzar in the year 1547, but it was expressly given to the sovereigns of Russia long before: this title in the Russian Bible signifies a king. In 1721 Peter I. assumed the appellation of emperor; and this imperial title has been borne ever since by the sovereigns of Russia. The abridged title, usual in ukases, sentences, commands, petitions, &c. is “emperor and autocrat, or empress and empress, of all Russia, or of all the Russias.” It is beside our purpose to discuss the question concerning the ancient origin, or even existence of fundamental laws of the empire: it will be sufficient to remark, that all the present laws of this kind may be reduced to two principal classes, as they ascertain either the authority and prerogatives of the sovereign, or the claims of the subjects. Those that regard the sovereign comprehend the hereditary succession, the uncircumscribed authority, including all the great and exclusive prerogatives of majesty, and the principle that the sovereign is an imperial majesty and the dominion an empire: those that regard the subjects include specific obligations and rights, and they concern either the empire at large, or particular tribes, ranks, and classes; such are security of person, of reputation, of property, the non-denial of justice, legal protection against violence and oppression, unmolested enjoyment of all lawfully obtained immunities, privileges, and rights; the right, on the extinction of the reigning family, if no successor be appointed, to elect one, &c. Accordingly, the nobility may justly demand the quiet enjoyment of all the privileges and immunities granted to them by letters of grace. The burghers may appeal to the privileges granted to them in the regulations for townships. The Don Cos-

sacks, and other nations of that kind, may justly expect that no invasion be made on their districts and possessions, or any infringement of their rights, &c.

The legislative authority is vested solely in the monarch; neither the whole nation as a body, nor single members or classes of it, can claim any part of it. The sovereign is also the sole dispenser of all ranks and dignities; to the higher he himself appoints the persons, and signs with his own hand the instrument or patent. The inferior degrees are bestowed in his name by the proper commissioners or boards, *e. g.* in the civil department by the senate, in the military by the college of war, in the navy by the admiralty, in the church by the synod, in the medical department by the college of medicine, &c. Formerly there were several monopolies of the crown; but the late empress, to the manifest advantage of her subjects, abolished the greater part of them, reserving only two, *viz.* salt and brandy. As to landed property in general, it belongs either to the crown, or to private owners, and that again either to individuals, or in common to a whole tribe. Another prerogative that adheres to the throne is that the sovereign can appoint a regency during the minority of his successor, and fix the period of his arriving at majority. The form of government in Russia is unlimited monarchy; however, the free-born Russian subjects are always treated as such; and in general, it is permitted the subjects to utter their complaints and to make a representation of them. From several ukases it appears, that the next successor, his consort, and all their children, are styled grand dukes and grand duchesses, and that they all bear the title of imperial highness; that it is conferred upon them always by a signed decree of the monarch, and that, respecting the grand-daughters, the terms grand duchess and grand ducal princess are sometimes synonymous. The rights of the grand duke, as heir apparent, do not seem to have been accurately defined; he is the first subject, but he has properly no functions arising from his high birth and appointment, these depending on the good pleasure of the sovereign. The princes and princesses of the reigning family have no settled establishment; their household depending on the pleasure of the sovereign. The annual allowance to the grand duke, it is said, is usually 220,000 rubles, and sometimes more, to which are added many great presents.

The arms in the middle ages were borrowed from Moscow, at that time the imperial residence, and consisted of St. George on horseback, killing a dragon with a spear. Ivan Vassilievitch made choice of a black spread eagle, with a crown on each head, a larger crown between them, in a golden field, and holding in one claw a sceptre, and in the other an imperial mound, with the arms of Moscow on the breast. Sometimes it is surrounded with a collar composed of the arms of some of the countries belonging to the Russian empire, as Altrachan, Kazan, Siberia, &c. This is accordingly the imperial seal, and when the late empress used it for letters, it had an imperial mantle, and over it an imperial crown. The court is composed of the great officers of state, of senators, actual privy-counsellors, princes, counts, barons, &c. On court-days access is open to every subject. Six orders of knighthood form a part of the splendour of the court, with their peculiar insignia. The first three were constituted by Peter I.; the two next by the late empress Catharine II., and the sixth proceeds from Sleswick-Holstein. Of the former five the monarch is always grand-master; but of the sixth, the grand duke, as duke of Sleswick-Holstein. To the fourth and fifth, pensions are annexed to a select number of the eldest knights. These orders take precedence according to the seniority of their

## RUSSIA.

their institution. They are as follow, St. Andrew, St. Catharine, St. Alexander Nefsky, St. George, Vladimir, St. Anne of Holstein. See each respectively.

Of the imperial colleges, instituted for the government of the Russian empire, our limits will allow our mention only of the two principal and supreme, *viz.* the "Directing Senate," and the "Holy Synod." The former was constituted by Peter I., who raised it to the rank of the supreme or highest college of the empire. In 1763 the late empress new-modelled it, causing it to consist of six departments, four at Petersburg and two at Moscow. This supreme imperial college, styled by the empress the sanctuary of the laws, can issue orders to any other imperial college, and receive reports from them (the synod excepted), it publishes the laws and edicts received from the monarch, and provides for their execution; returns a decisive answer to the questions sent in by the courts or governors in doubtful cases; appoints to many considerable posts in the viceroalties; advances, in the name of the sovereign, meritorious civil officers to higher rank, and is the highest tribunal to which appeal can be made, for none can either appeal from its decrees nor complain of them; but any one who is dissatisfied with its sentence has no other resource than to present his petition to the cabinet. The second supreme college is the "Holy Directing Synod," which is the highest spiritual court of the Russo-Greek church. In 1789 this college consisted of one metropolitan, one archbishop, one bishop, one proto-pope (the imperial confessor), one archimandrite, one proto-pope (of the seculars), one upper procureur, one chief secretary, one executor, three secretaries, one protocolist, and one staff-surgeon; the absent members were one metropolitan, two archbishops, and one bishop. At the synodal comptoir at Moscow, at that time, were one metropolitan, one arch-priest of the secular clergy, one procureur, and one secretary. In the spiritual commission, one metropolitan, one archbishop, one privy-counsellor, and one secretary, have their seats. Under the authority of the synod are all prelates, consistories, ecclesiastics, churches, religious books, &c. For the other subordinate imperial colleges, we refer to Mr. Tooke's account of them; as well as for other particulars relating to the laws, the constitution of the Russian government, and the condition of the Russian subjects. On this latter topic we shall select and subjoin a few particulars.

The nobleman, generally speaking, pays no tax for any part of his land which he occupies himself, nor even for his moveable property. If he possess no male vassals, his fields, forests, mines, mills, fisheries, &c. which he occupies with free or hired labourers, are as exempt from taxation as his person; but, on the other hand, the nobleman who has vassals must furnish recruits out of them. The clergy, in regard to their persons, are likewise exempt from taxes. Their stipends, which consist in money, and in the country of corn and pieces of land, are raised by them free of all deductions. Placemen, and officers of the crown, &c. pay no annual tax on their salaries. Literary men, who are not enrolled in any guild, and who, besides their learned profession, as physicians, lawyers, &c. are not engaged in trade, are entirely exempt from taxes; and this is also the case with artists, &c. People who live solely on the interest of their capital, and do not inscribe themselves in any guild, however large their income may be, pay no tax upon it whatever. All inhabitants of towns possess their immoveable property free of all taxation. As for the great body of the yeomanry or country-folk, their real necessaries are subject to no taxes, because in all Russia there is no such thing as excise; and in general the taxes are not oppressive. That

both the nobility and burghers live in affluence is manifest from the luxury that every where prevails. The Russian boor, even the vassal of the nobleman, lives very decently in his house, has a sufficiency of wholesome food, is neatly dressed, puts commonly two or three dishes on his table, and even accumulates a trifling capital, though, as it is not secured to him, and may be taken from him, he frequently buries it in the ground. In some villages the boors display even an opulence. Among the very numerous nobility many possess fortunes of 100,000 or 500,000 rubles, and sometimes more; and the generality may have a fortune of between 30,000 and 100,000 rubles. In no country are the learned professions so well provided for as in some provinces of Russia, particularly Livonia and Esthonia. The preacher, even in the smallest country-pastorate, lives on a footing no less brilliant than the general superintendant in many of the provinces of Germany. Although his stipend is small, yet his presents for the discharge of his official duties from noblemen and burghers are numerous and large. His daily table is supplied with several dishes; he has men servants and maid servants; he is commonly the friend and confidant of the noblemen of his parish, and his house is the place of their usual resort. The case is similar with regard to law-advocates, physicians, surgeons, and private tutors. On account of the flourishing state of commerce in the maritime towns, there are many merchants who possess capitals of some hundred thousands of rubles. The condition of the boors is far from being contemptible and wretched. The Cossacks generally enjoy not only the necessaries but the accommodations and comforts of life. In the parts about the Don, ease and affluence are every where seen; and the Cossacks of the Ural pass their time in idleness and yet in plenty from the riches obtained by means of the productive fisheries on that river. Upon the whole, the writer now cited observes, that the moderate taxes, the cheap living, the excellent and numerous products, the contentedness of the people, and the good regulations adopted through the empire, afford to every one who conducts himself well in his state of life, sufficient means for acquiring a competency. The majority of the Russian subjects fare better in their way than the great multitudes in France, Germany, Sweden, and several other countries.

The social state of the inhabitants of the Russian empire is capable of great melioration, and productive of much actual comfort, from the opportunities that are afforded them for active and industrious exertions. The objects of the *chace*, in the most northern and eastern parts of Russia, and particularly on the islands between Kamtschatka and America, and also in the governments of Tobolsk, Perm, Ufa, Vietka, Archangel, Olonetz, Vologda, and some others, afford both an amusing and lucrative employment. The *chace*, for the sake of furs, is of primary importance in its relation to foreign commerce. The most valuable of all the animals that are sought for their skin is the "sable," the skin serving as a standard to the tribute, which is paid to the crown by the Siberian nation of hunters. This animal is found in Asiatic Russia, from the Aleutan islands and from Kamtschatka to the districts of the Petsehora and of the Kama. The finest sables come from Yakutsk and Nertselinsk; and among these are likewise, though rarely, yellow, and very seldom, white sables. The Kamtschatka sables are the largest of all. As the sable is become scarce, the crown accepts of the skins of foxes, martens, squirrels, and fish-otters, from the inhabitants of Siberia, instead of the sable. Eastern Siberia, and particularly Kamtschatka, abound most in beautiful foxes. To the other objects of *chace* for the furs, we must add the bear, the wolf, the lynx, the

the glutton, the ferret, the pole-cat, &c. which, generally speaking, are spread over the whole of North Russia; and vast quantities of their skins are either consumed at home or sent abroad. But we have not room to enumerate all the animals that are profitable objects of chase to the Russians. We shall observe in general, that peltry of all kinds may be considered as a remarkable and lucrative product of the Russian empire. The principal species are: fables, beavers, blue and white foxes, wolves, hyænas, lynxes, ermines, peitzui or muscovite dogs, squirrels, martens, hares, sheep, wild cats, panthers, tigers, and bears. The Russians have the art of dyeing the furs so ingeniously, that the Chinese, and therefore others who are not good judges, are easily cheated.

Beavers are chiefly found in Kamtschatka; they are principally used in trimming the caps and pelisses of women of quality.

Foxes are every where met with in Russia proper, in the conquered provinces, and in Siberia. Those of Siberia are the best. Besides the common cross-blue fox, they have very dark, called black, and even white foxes, which last, however, are extremely rare, and, like the black, fetch a higher price than fables. The ermine is a sort of rat, and is employed for trimming pelisses. All minever is squirrel-skin. The Siberian is incomparably darker, thicker, and more lasting, and accordingly much dearer than the ordinary Russian. The Russian hare-skin is of the hare peculiar to this country, which in winter becomes white. The russaki cannot be used as fur, as they never change their colour. Common coarse sheep-skin affords a warm and durable pelisse for the lower order of people; the finer is worn even by persons of distinction. The Kalmuck and Bucharian sheep-furs are rather scarce and dear, still more so are the Kalmuck furs of unborn lambs. The genuine Bucharian sheep-skins are watered, and the Kalmuckian by nature crisp and curly. But here likewise great frauds are practised, as the Russians frequently curl the fine skins of the common sort, in order to impose upon the unwary.

Bear-skins and tiger-skins are used only for covers to sledges, and trappings for horses, or, instead of beds, for servants to lie on. Boots are lined with the ordinary Russian cat-skin; but the blue Siberian cats yield a very beautiful fur.

All these skins are sold either by the piece or sackwise. Two hundred skins of Russian, and a hundred skins of Siberian minever, compose a sack, and two hundred hare-skins are also reckoned a sack. The Russians are singularly industrious and ingenious in assorting their furs. Of one sort of skin they make several descriptions of furs; as, for example, a particular fur is prepared of the small dark stripe on the backs of squirrels, another of the sides, again another of the bellies; and in like manner with the skins of other animals.

Besides the chase, which has always been the exclusive occupation of particular nations of the Russian empire, there are also tribes who maintain themselves principally or wholly by the *fishery*, and with whom even the establishment of this trade forms a part of their civil constitution. Some follow it for their own support, while others, as the Cossacks of the Don and the Ural, and the tribes on the shores of the Volga, carry on a lucrative traffic with the products of their fishery. The Frozen ocean, together with its bays and rivers, affords various species of sea-animals, that are sought after by several nations. To the inhabitants of the governments of Archangel and Olonetz the islands of Spitzbergen and Novaya Zemlia afford the chief scene of fishery at the proper season. The animals that principally engage their attention are whales and morse. Accordingly, every year a ship goes

from Archangel to winter at Spitzbergen, and at least one, frequently more, to Novaya Zemlia. The inhabitants of Mese navigate these coasts only in summer. From the morse fishery the chief commercial products are the blubber and the skin; the blubber for its oil, and the skins, when dried, for horse traces, and when cut, as size for the paper-manufactories. The teeth of the morse likewise are transported to Petersburg, Mese, and Archangel, and are wrought up into the various works for which ivory can be used. The Frozen ocean also teems with the narwhal, the pott-fish, from whose brain spermaceti is prepared, the sea-dog, dolphin, sea-hog (delphinus phocæna), hay-fish (squalus carcharias), sea-cow (trichechus manatus), the sea-bear (phoca urfina), the sea-lion (phoca leonina jubata), the sea-otter (lutra marina), and many others, which are caught either for their skin or their blubber. Among the principal objects of the fishery on the coasts of the White sea, which skirt the government of Archangel, are the cod, the navaga (gadus callarias), plaice, soals, stock-fish, and herrings. The Dvina and the Petthora abound in that excellent fish called by the Russians *sighi* and *salmons*, the latter being reckoned the fattest and best flavoured of all Northern Russia, and they are therefore frozen or salted, in order to be transported to a great distance round the country. The Oby also affords an ample supply of sturgeons, sterlet, white salmon, pikes, muræna, quobbe or quappe (gadus lota), and a multitude of other fish. The Oby fishery is chiefly carried on by Ostiaks and Samoyedes. The Irutisch also contains almost all the fish that are found in the Oby; and here the fishery is very considerable. The Yenissei and Lena, and most of the rivers that fall into them, furnish great variety and abundance of fish. The whale fishery we shall have occasion to mention under another article. The Eastern ocean furnishes, besides the whale, the sea-bear, sea-lion, sea-cow, and sea-otter, which we shall elsewhere describe. In a commercial view, there is not any of these marine animals so important as the sea-otter, the beautiful fur of which is in high estimation. See FUR.

The fishery on the Caspian, as Pallas observes, is in some respects as important to Russia, as the herring, the cod, and the whale fishery to other maritime powers of Europe. Of the fish of the Volga, the several kinds of sturgeon and the white salmon are the best. The Kamma, which falls into the Volga, also abounds with fish, which is held to be the best flavoured of any in Russia, at least its sturgeon, sterlet, and white salmon, are preferable to those of the Volga. Besides these three kinds, a principal fish of the Kamma is a small salmon called in Rus *krafnaya reba*, red or beautiful fish (*salmo eriox*, or *salmo alpinus*). For an account of the means for catching fish on the Volga, and on the confines of Astrachan, see UTSCHING. The fishery on the Ural is not less considerable than that of the Volga; and being under good regulation, it forms the principal support and occupation of the Uralian Cossacks. See URAL.

The fishery of the Euxine and the sea of Azof, though neither so important nor extensive as that of the Caspian, affords numerous sorts of sturgeon. The whole northern coast of the sea of Azof, from the Don to Perekop, is laid out in fisheries, for which these districts are extremely favourable. The most considerable fisheries on the peninsula of Taurida are at Kerth and Yenicaly, where the capture usually begins in May, and continues till some time in October. On the coasts of the Baltic, also, a considerable fishery is carried on. The gulfs of Riga and of Finland contain generally the same kinds of fish. In the waters of Livonia, says a naturalist of that country, are forty-nine different species of fish, among which the salmon, streamlings, pike, and lampreys,

preys, for exportation if not for home consumption, are the most important. One species of fish peculiar to these waters is the kyllo streamling, caught in great numbers in autumn, near Revel and Roggervyk. They are pickled, and form a good substitute for anchovies and fardelles, and thus prepared, they are sent abroad to various parts. The potted lampreys from Narva are no less exquisite. The greatest store of the gulf of Finland consists of sterlets, salmon, and carp. Sturgeon are found in the gulf of Cronstadt, and likewise at times in the Neva. In winter, the transport of frozen fish from the remotest parts of the empire to St. Petersburg is very considerable. In Russia there are several lakes that afford an abundant supply of fish. The chief of these is the *Baikal*, which see. The Tschan, a Siberian lake, is particularly prolific in fish; and in this respect among the European lakes the Ladoga is the most remarkable. The Peipus and the Ilmen also yield a great variety of fish, and the smaller European lakes are proportionally productive. According to the calculations of Hermann, the whole value of the fishery in one year, may be estimated at 15,000,000 of rubles.

Another branch of productive industry in the Russian empire is the *breeding of cattle*. The nations of herdsmen in this empire are the Kirghises, the Kalmucks, the Baschkirs, the Burats, and several others less numerous: the breeding of cattle is a principal trade with the Cossacks of the Don, the Nogayans, the Barabinses, and some others; with most of the nations of hunters it is a considerable means of profit, and as a profitable branch of trade it flourishes in many districts of proper Russia. The breeding of cattle affords to the inhabitants many, and in some districts all the means of subsistence, and yields besides to commerce a multitude of articles for exportation. Two of these are hides and tallow: of the latter, in the year 1793, 1,035,000 poods were exported; and the value of that quantity amounted to 4,279,000 rubles, not including the tallow candles, the exportation of which amounted in value to 170,000 rubles. Yufts and leather were in the same year shipped off to the amount of 2,249,000 rubles, and the other exports in the products arising from the breeding of horned cattle, made a sum of more than 163,000 rubles. The whole value of all these articles in one year was upwards of 6,862,000 rubles. The breeding of sheep is also an article of importance in the Russian empire. The Nomades are richer in sheep than in any other article, and even the boors and Cossacks in Southern Russia and Siberia possess flocks of hundreds and thousands. Through the whole country this branch of productive industry might be very much improved. Goats and hogs are also animals that yield to the Russian empire considerable profit, and with due attention might be rendered much more lucrative. Hog's bristles constitute an important article of exportation; in the year 1793, these, to the value of 742,000 rubles, were shipped off. The horse, the ass, the camel, the rein-deer, and the dog, are animals which are capable of being rendered profitable to this country in a much greater degree than they now are; though at present they are not unworthy of attention.

Another branch of productive industry in the Russian empire is *agriculture*. In Russia, agriculture is less the business of the peasantry than in other countries. Throughout the empire every village has its proper territory, and every estate its allotted inclosures and commons. In Siberia every man takes as much ground from the open steppes as he can manage; and when such a portion of ground is exhausted, he proceeds to another, &c. so that these little slips of land lie scattered at twenty, fifty, and even eighty versts distance from the village. In Russia and Siberia they cultivate win-

ter rye and summer rye, winter wheat only in Russia as far as the Kama, summer wheat both in Russia and Siberia; barley, spelt-barley, or bear-barley plentifully in Russia; oats in Russia and Siberia; few pease, and still fewer vetches and beans; a great deal of buck-wheat; in Siberia, Tartarian buck-wheat, millet, and the grain called panicum germanicum, only in Russia. The villagers have hay-fields on the banks of lakes and rivers, in brakes and fens of the forests. The old withered grafs, weeds, twigs, and light stuff they set on fire, and this occasions an appearance which at night is tremendous. Besides corn, they grow flax in large quantities, chiefly on the Volga, but most of all in the government of Yaroslaf, and also in the governments of Moscow and Kazan. Hemp is indigenous in all the south and middle of Russia and Siberia, and is propagated in great abundance, both for the material of linen, sail-cloth, &c. and for the oil expressed from its seed, of which a very great quantity is consumed for food during the falls, and which, as well as the hemp, is exported annually to a great amount. Woad likewise grows wild in Southern Russia and Siberia; it is gathered in the Ukraine, and employed in staining and dyeing. It is also cultivated in the government of Penza, and about the Don. Tobacco is planted almost solely, but in great abundance, in the Ukraine. Hops are propagated by the villagers only, in small quantities, in the governments of Kazan, Nishnei-Novgorod, &c.; and in Siberia, in the province of Irkutsk, the wild sort is plentiful. Orchards are of little account, except in the chief towns. No fruit-trees thrive in Siberia. Water-melons are much cultivated in the south-eastern parts of Russia, from the Don to the Ural, especially on the Volga. In the breeding of cattle, the countryman is directed by climate and pasturage. In the south of Siberia a person often possesses 300 horses, as many sheep, about half the number of horned cattle, always a few swine, and much poultry, sometimes geese and ducks. The Russian horses are of a middling size, with large heads, long slabby ears, not very handsome, but spirited, strong, and hardy. The horned cattle are small and brisk: the cows give little milk, which is poor and thin. In Little Russia the oxen are used for draught. About Archangel there is a fine breed of large cows, originally brought from Holland, and they do not degenerate. The true Russian sheep are distinguished from the common sort by a short tail, about the length of seven inches. Hogs, dogs, and cats are of the ordinary kinds. The poultry are housed all the winter in the cottage, under the hearth and the sleeping benches, for the sake of having Easter eggs. The culture of bees is the principal concern of the Baschkirs in the Ural, and is also an object of attention in Southern Russia. In the northern districts of Russia and Siberia the elace is pursued as a trade, particularly for those animals whose skins are used as furs, especially sables and grey squirrels, for the wear of the Russian gentry in town and country. The carrier's trade is a source of great profit. The towns at the distance of from 500 to 1000 versts, serve as stations for changing the drivers and carriages, *e. g.* from Kiachta, Irkutsk, Krasnoiarfsk, Tomsk, Tara, Ekaterinenburg, &c. The country market-towns and hamlets are commonly open, and mostly built in irregular streets, with little kitchen-gardens and large yards to the houses; they are situated on the banks of rivers, for the convenience of obtaining water. They contain many churches; and the monasteries in or near them, from their strong walls, massy gates, and numerous church towers, have the appearance of castles. The fortresses dispersed about the country have seldom earth-ramparts, but are mostly built like their houses, with a low palisade round them. The cannons stand on the gates and on the angles of the ramparts,

or batteries on wooden carriages. These are designed to keep the tributary tribes in awe, and the neighbouring Nomades from the borders. Ostrogs, or houses surrounded with a palisade of upright pointed banks, are situated either in towns, where they serve as prisons for criminals, or solitarily, in various parts of the country, for the same purposes as the fortresses. The parishes, or church villages, are sometimes very extensive; containing 500 or even 1000 and more farms, and from three to seven churches, many of them brick buildings, markets, and trafficking places. Large villages are frequently called slobodes, but many slobodes are less than church villages; the houses are ranged in straight streets, and the streets mostly laid with timbers.

Of the nations, says Mr. Tooke, who have followed agriculture from time immemorial, though in various ways, and with different success, the principal are the Russians, the Poles, the Lithuanians, the Lettes, the Finns, and Esthonians. The state of agriculture in all countries must depend on the nature of the soil and climate, as well as on the industry of the inhabitants. With this view of Russia, the most northern and eastern districts of the empire, of the former, particularly in Siberia, are totally unfit for every kind of economical culture. The 60th degree of latitude may be regarded as the boundary beyond which no agriculture is practicable. The repeated attempts that have been made about Okhotsk (between 59° and 60° N. lat. and 160° E. long.), and Udskoy-ostrog (55° 20' N. lat. and 150° 40' E. long.), in the government of Irkutsk, shew, that the culture of corn will never be introduced to effect; and even in Kamtschatka, where the southernmost cape runs out to 51° N. lat. similar trials have been made with very poor and precarious effects. Admitting, therefore, the 60th degree of latitude to be the general boundary of the soil susceptible of culture to the north, we may infer, that the Russian empire contains about 162,000 square geographical miles of land totally unserviceable to the purposes of agriculture. Accordingly the circles in the governments of Olonetz and Archangel have no agriculture, and even in some districts of Vyborg, St. Petersburg, Novgorod, Vologda, Perm, and Viatka, it is attended with almost insuperable, or at least deterring difficulties. In some also of the southern districts of Caucasus, Saratof, Ufa, Kolyvan, Ekaterinofslaf, and Taurida, the soil is so poor, that the natural impediments can perhaps never be entirely surmounted. To the fertile regions belong most of the governments of the middle, and several of the northern tracts; but the best and most productive soils are chiefly found in Little Russia, Kazan, Simbirsk, Kharkof, Kursk, Orel, Nishnei-Novgorod, in the southern part of Taurida and Caucasus, and in the newly-acquired portion of the Polish Ukraine, and particularly also in some of the Siberian provinces. The great fertility of the districts bordering on the Volga, the Kama, the Dnieper, the Terek, and the parts about the Euxine, has been long experienced. Moreover, in the territory of Krasnoiarsk, a circle-town of the government of Kolyvan, between the 55th and 56th degrees of N. lat., the fertility of the soil is such, that no instance has occurred of a general failure, and that it is a very ordinary harvest, when the summer rye yields 10-fold, the winter corn 8-fold, and the barley 12-fold. It is usual for the wheat only in bad years to yield the sixth grain, and the oats give an increase rarely short of 20-fold. In consequence of this exuberance, provisions are here in great plenty, and probably in no province of the empire at so low a price. When Pallas was at Krasnoiarsk, a pood of rye-meal sold for 2 or 3, and a pood of wheaten flour for 4½ or 5 kopecks; a whole ox was bought for 1½ ruble, a cow

for a ruble, and a good serviceable horse for 2 or 3 rubles at most; sheep and hogs fetched from 30 to 50 kopecks a-piece. And though in 25 years that have elapsed since that period an alteration has taken place, yet this country is still one of the cheapest, as well as one of the richest and most plentiful of all.

The implements of husbandry, without which no great progress in the culture of the soil can be expected, are the most simple and artless that can be well imagined.

In such a state, and with such instruments, we need not wonder that agriculture is negligently and badly conducted, and yet we may well be surpris'd, that the country so managed should yield so considerable a produce; the bounty of nature supplying the work of skill in most of the provinces of middle and southern Russia. Moreover, in the provinces lying in the Baltic, in the White-Russian governments, in the Polish Ukraine, and even in proper Russia, on the estates of noblemen who carry on the farming business with some degree of care, much greater pains are bestowed, and in general more ingenious implements are used. It would lead us too far to give an account of the practice of husbandry either in the northern or southern provinces of Russia; yet, in spite of all the defects of Russian agriculture, its products are so numerous and important, that they not only supply the home consumption, but constitute by far the most considerable article of exportation. The corn most generally cultivated in Russia, and in those tracts of land that do not lie farther north than the 60th degree of latitude, is rye: wheat is more cultivated in the middle and southern governments; in the government of Ekaterinofslaf is cultivated the "Arnautan" wheat, which yields a yellowish flour, and which produces in good years 15 corns above the sowing. Turkish wheat, or maize, is raised on the confines of the Terek and in Taurida. Barley is also a considerable produce of governments in which wheat succeeds, and oats also are cultivated for the consumption of the people in meal for porridge.

Of the four kinds of corn now enumerated, Russia annually exports a considerable quantity, especially from the Livonian ports. The Livonian corn is said to keep longer than that of other countries, not to need such frequent turning, and likewise to yield more flour. In 1793 these exports amounted, in corn and meal, to the value in wheat, of 1,490,000; in rye, of 1,379,000; in barley, of 236,000; and in oats, of 17,000 rubles. The other corns cultivated for home consumption, but not for exportation, are millet, spelt or bear-barley, buck-wheat, manna, or testuca fluitans, growing almost every where in Russia, on meadow-grounds that are overflowed, particularly in the governments of Riga, Pfcove, Polotsk, Novgorod, Tver, Smolensk, &c. and rice. Potatoes are cultivated only in a few governments, and chiefly among foreign colonists. Grasses, and fodder of all kinds, every where abound in the Russian empire; and vegetables, for the use of manufactures and commerce, are very abundant, such as hemp, of the produce of which the export, in 1793, amounted to upwards of 8,808,000 rubles; without including the hemp-oil. Flax of the best kind, and most in quantity, is cultivated in the governments of Vologda, Pfcove, Novgorod, Riga, Mohilef, Tver, Polotsk, Viatka, the confines of the middle Volga, and in the parts about the Oka and Kama. Both the common and the Siberian flax are often found wild, the former in the steppes, about the northern Ural, the latter on the shores of the Volga, near Tzaritzin, and in other places. Among the plants growing wild, and yielding fibres like flax or hemp, is also the common and the Siberian stinging-nettle (*urtica dioica* and *cannabina*), which are found plentiful on the Uralian mountains.

mountains. The Bafchkirs, the Koibals, the Sagayan Tartars, &c. prepare yarn and weave linen of them. Of flax, in seeds and other products, exclusively of the oil, the exportation in 1793 amounted to 7,220,000 rubles. Cotton has hitherto been little cultivated; some attempts have been made about Astrachan and Kitzliar, on the Terek; but there are other climates and soils that would suit it. Some wild-growing silk-plants, yielding a material similar to cotton, known among botanists by the name of "cynanchum acutum," and "apocynum maritimum," grow wild in the worst soils, and might be cultivated and manufactured to advantage. There are also other plants of a similar kind that might become objects of profitable attention. Russia also furnishes a variety of plants that would afford, if duly regarded, abundance of dyeing materials; such as madder, which grows wild on the banks of the Oka, near Riazan and Arfamas, on the borders of the Volga, in the confines of Syfran and Saratof, and in great quantities, and of superior quality, about the Samara, in Taurida, on the Terek, and in several districts of the government of Caucasus; woad (*isatis tinctoria*), and a variety of it (*isatis lusitanica*), which are seen wild in several of the southern governments; saffron, which grows wild about the Terek, in the governments of Voronetch and Ekaterinoslaf, in Taurida, and especially in the Caucasian mountains, around Mosdok; and safflower (*carthamus tinctorius*), which thrives perfectly well in the gardens at Toropetz, Moscow, Tzaritzin, Poltava, and other places. Among the vegetables for fabrication and trade, we might enumerate hops and tobacco; the former grows wild in most districts of Russia and Siberia, and the latter is cultivated in the Malo-Russian governments, and also about the Volga and the Samara, and particularly by the Cossacks on the Orenburg and Siberian lines.

In 1793 the exportation from Russia of hemp-oil and flax-oil exceeded in value 697,000 rubles.

Of medicinal plants of all kinds, Russia possesses a great store; such are the rhubarb (*rheum compactum*), and the rhapontic, or Siberian rhubarb (*rheum undulatum*). Sassafras (*saxifraga crassifolia*) grows abundantly in the southern and lofty snow-mountains of Kolyvan; and the polypodium fragrans, a beautiful and odoriferous fern, is gathered by the Burzts on the summits of rocks, and is taken as a wholesome tea against scorbutic and colicky complaints. The culinary vegetables that are cultivated in Russia are so numerous and various, that it is needless to mention them. Besides those shrubs and berries known to us, such as raspberries, currants, strawberries, which grow in surprising quantities, gooseberries, &c. Russia produces in great abundance several which are here very rarely or never seen. Of these, for instance, are the berries called *pianitza*. In appearance they are much like the bilberry, but have a very different, exceedingly agreeable taste, and intoxicate if taken in quantities. Hence it is they have their appellation, from *pian*, drunk. Mushrooms are found in great plenty, and are very generally eaten, excepting the champignon, which, for what reason it is not easy to discover, is carefully avoided by the common people. Of the Russian mushrooms, the *rishchicki* or *ritzgen* are most famous. This sort of mushroom is likewise found in Courland and Prussia. Their name, *rishchicki*, is derived from their reddish-yellow hue; and they are eaten either raw, boiled or broiled, or pickled. We shall further select some other vegetables that have engaged more than ordinary attention: such are asparagus, which in the government of Moscow, and some others, is made an article of trade; such are berries of various kinds, some of which are peculiar to the north of Russia, as well as to the whole of Siberia; the hazle-bush, found over all Russia as far as the

Kamma, and so plentiful in the regions between Simbirsk and Kazan, as to give rise to a branch of considerable trade, as a great part of Russia and all Siberia are hence supplied with a sweet-meat in very general use, eaten in the fats with nut-oil; sugar-melons and water-melons, which thrive in the open air to the 52d degree of latitude; the common orchard fruits, which succeed every where in the middle and southern parts of Russia. Of all the species of fruit produced in the Russian empire, apples and pears are the most abundant. All the villages on the Oka and Volga have their orchards, or more properly apple-gardens, so that many boors live here without husbandry, merely by horticulture, in good circumstances. Cherries are very frequently produced in orchards, but in Southern Russia there are even whole forests of cherry-trees. Apricots and peaches succeed in most parts of Taurida and Caucasus, and in the southern circles of Kief, Ekaterinoslaf, Vofnefsk, and some other governments, without much attention. The quince-tree grows wild and plentifully in the forests about the Terek: chestnut-trees are only found singly in Taurida, Kief, and Voronetch; walnut-trees are seen in most districts of Southern Russia, and in great abundance; but the almond-tree grows only in the provinces that lie most to the south: figs and pomegranate-trees are seen singly near Kitzliar and in Taurida; but lemons and orange-trees are every where raised only in hot-houses, though Pallas assures us, that they would very well bear the winter in Taurida with more attention. The culture of the vine is at present carried on in the governments of Caucasus, Taurida, Ekaterinoslaf, and Vofnefsk, and the country of the Don Cossacks. The whole region of the Russian empire, from the southernmost borders to the 48th degree of latitude, constitutes a superficies of more than 12,000 square geographical miles; but of this large tract, scarcely one-fourth part is proper for the culture of the vine.

The forests of Russia amount to a superfluous abundance in the governments of Archangel, Olonetz, Tobolsk, and Irkutsk: the governments of Perm, Kazan, Smolensk, Mohilef, Minsk, Tchernigof, Voronetch, Ufa, Tula, Simbirsk, Orel, Kaluga, &c. are richly furnished with them, not only supplying most of the forges and metal founderies, but also sending excellent ship-timber to the yards. Most of the other provinces have a sufficiency for their own consumption; but some few of the southern governments, as Kief, Kharkof, Kurfk, Ekaterinoslaf, and Taurida, are but scantily provided. Of trees, those that have narrow-pointed leaves are chiefly indigenous in Northern Russia, forming forests of prodigious extent, among which the fir, the pine, and the black pine, are the most common and most widely diffused. The Siberian cedar (*pinus cembra*) is found particularly in the Uralian mountains; the larch-tree grows in the north of European Russia, and in most of the Siberian mountains. Among the umbrageous trees the birch is the most common, and its bark and wood are applied to various purposes. Next to the birch is the linden, from which Russia derives great advantage. The oak is indigenous only in the European part: it is most frequently found in the governments of Kazan and Voronetch, where it is chiefly employed in ship-building; but also in Little and White Russia it forms considerable forests. The ash and the willow grow almost every where: but beech, elms, the maple, and the poplar, are chiefly the growth of the southern regions. The forests supply an extraordinary number of products for home consumption, and also very considerable articles of export. In 1793 the value of the latter in specie amounted to upwards of 2½ millions of rubles, when Russia shipped off to the value of 1,744,000 rubles in masts, barks, and deals; 394,000 in pot-ashes and barilla;

## RUSSIA.

barilla; 249,000 rubles in mats, and 150,000 rubles in pitch, tar, and resin.

The Russian woods consist of limes, firs, pines, birch and larch-trees (*larix*), to which may be added some cedars. The beech and the oak are rarely seen, excepting in Kazan, where the oaks appear pretty plentifully. For ship-building the larch-tree is generally used, though some vessels are constructed of oak, which is brought at an almost incredible expence from the territory of Kazan to the yard of St. Petersburg. The larch, which in other countries is classed among the evergreens, is deciduous in Siberia. Besides the astonishing quantity of wood that is consumed as fuel, Russia has ample supplies of timber for construction. For, throughout the whole empire, excepting St. Petersburg, and a very few other places, the houses and churches are almost all of timber. And even at St. Petersburg great numbers of them are still seen, though, in pursuance of an express imperial edict, no new ones are to be built. These timber houses are extremely well adapted to the Russian climate, as being much warmer than those constructed of brick and stone. Both in towns and villages the same mode of building is uniformly practised. One balk is laid upon another to the height intended. The roof is formed either of boards or oak shingles; and the interstices between the balks are crammed with moss. The Russian carpenters, in the whole construction of a house, employ no other tool than an axe, and a sharp circular iron, with which they shave off the bark from the timber. With the axe alone they carve the ornamental comb or crest (*greben*), which is frequently wrought with exquisite ingenuity, and carried along the ridge of the roof. It appears strange to the foreigner that they never work without gloves, yet always, even in winter, go bare-headed. The generality of houses are only of one story; if they have another, as is occasionally seen in towns, the staircase is usually run up on the outside. In the houses of the boors, as well as those of the citizens, unless they are in good circumstances, are square holes instead of windows, provided with a wooden shutter. Sometimes these apertures are furnished with a hog's bladder, through which the light enters. Only boors of property have windows of singlafs. The boors' houses regularly consist of one room; which is at the same time kitchen, cellar, hog-stye, and the habitation of the whole family; together with the tutelary saints, who have their tabernacle in one corner of the upper part of the apartment, commonly however so encrusted with smoke as hardly to be cognizable. The boor, with all his inmates, customarily during the winter lodges on the shelves fastened to the walls about the stove which heats his room, and which serves also as an oven for dressing his victuals. Here they constantly sleep, winter and summer, without beds or other accommodations. In all the boor-houses the door of the room is uncommonly low. On account of the abundance of timber, and the cheapness of provisions, and consequently the moderate price of labour, building in Russia is not expensive. For five hundred rubles the burgher builds himself a house of five rooms, with an ice-cellar, stable, a bathing-room, and the necessary offices. The burgher-houses have withinside a somewhat better appearance than the houses of the boors; the walls within, and frequently without, being chipped smooth and whitened over with a sort of wash used for smearing their stoves, and which dries much faster than mortar. Houses in Russia are reckoned among the moveables, and in every town there is a house-market, where a man bargains for a house, packs it upon sledges, and sets it up wherever he chuses. Such a house will last thirty years, and often longer. Convenient, however, as these timber edifices are in several respects, they are

hazardous in another point of view; since they may be considered as the occasion of such frequent conflagrations as happen in no other country; for, notwithstanding that in towns the houses stand pretty distant from each other, yet there never passes a year in which a very considerable number is not a prey to the flames. This is the less surprising on being informed that the common people generally stick a fir lath (*luchine*) into the wall, lighted at the projecting extremity, as a substitute for a candle, and that the precautions against fires, in the Russian provinces, are none of the best. Mr. Tooke says, that he has himself seen, more than once, in a provincial town, on a calm day at high noon, above 130, and at one time, upwards of 200 houses on fire. The number would certainly have been much smaller, if the houses had not been of wood, and proper precautions had been taken.

Besides the important advantages that Russia obtains from its wood, in regard of fuel and building, this product is profitable in several other ways, particularly in the preparation of potash. The rind of the numerous lindens that grow in the districts of Kazan and Astrachan is usefully employed in the manufacture of basket-work of all kinds; of which, as well as of mats and deals, Russia annually exports to a great amount.

As the mines constitute an object of great importance in the Russian empire, we shall here subjoin, from the work cited at the close of this article, an abridged account of them. The largest works of this kind are at present carried on in the Uralian, the Altayan, and Nertschinskian mineral mountains; the iron and copper mines of Olonetz, and those in several other parts of the empire, being of comparatively less importance. In the Uralian mountains are gold, iron, and copper mines, which latter are some of the most important in the empire. The Altayan mountains contain the richest gold and silver shafts, also veins of lead, copper, and iron, impregnated with gold and silver. But in the Nertschinskian mountains are very rich mines of lead, containing gold and silver. The discovery of these shafts, as well as the origin of the proper mine-working in Russia, is of no older date than the beginning of the last century. The art of mining, which had its rise in the reign of Peter the Great, was protected and encouraged in the year 1716 by a manifesto; and in 1719 he instituted the college of mines. In the reign of the empress Anna, and under the empress Elizabeth, the Russian mines acquired increasing importance and value; but their most brilliant era was the reign of Catharine II. The gold mines belonging to the Russian empire are properly two; *viz.* that of Beresof near Ekaterinenburg, on the Ural, which is by far the most material, and the Voytzer gold mines in the mountains of Olonetz. The most important silver mines are those of Kolyvan, in the mineral mountains of Altay. The silver, or rather the auriferous and argentiferous lead mines of Nertschinsk, have been wrought ever since the discovery of them in 1704.

From statements, which we cannot here detail, it appears that in the interval between 1704 and 1788, there were gained at all the gold and silver mines about 1000 pood of gold, and about 36,000 pood of silver, amounting together in value to upwards of 45,000,000 of rubles, on which the expences were not more than 15,000,000 of rubles.

The most important copper mines are principally in the Uralian, Altayan, and Olonetzian mountains. The entire annual amount of the copper obtained from them is about 200,000 pood; the value of which in money, reckoning the pood only at 10 rubles, makes a sum of 2,000,000 of rubles.

The iron mines form, next to the salt-works, the greatest portion

portion of all Russia's mineral wealth: the most numerous and rich of these are found in the Uralian mountains; and besides these there are two smelting-houses in the Altayan and Sayane mountains, and several in the governments of Olonetz, Vologda, Nishnei-Novgorod, Kostroma, Kurfk, Tula, Tambof, &c. We may allow for the whole empire about 100 forges, and 800 hammers. In the whole empire about 5,000,000 pood of iron are annually produced, which in specie amounts at least to 4,500,000 of rubles.

By the present constitution, the mines belong either to the crown, to public institutions, or to private individuals. The first possesses all the before-mentioned gold and silver mines: the share it has in the copper and iron mines is not accurately ascertained, but, according to authentic statements, concluded to be about  $\frac{1}{4}$ th of the former, and  $\frac{1}{8}$ th part of the latter. The crown mines, which were formerly under the superintendance of the mine college, have, since the abolition of that college in 1784, belonged either to the cabinet or to the senate. The gold and silver mines of Kolyvan and Nertschinsk are under the direction of the former, and the rest of the crown mines are dependant on the senate. The only public institution hitherto in possession of mines is the "Imperial Allignation Bank," which purchased the copper and iron works in the government of Perm. The private mines have received so many grants by law, that it is not easy to assign to individuals their respective rights and immunities. The private owners of mines are mostly nobles, but some are burghers and merchants. The works at the mines of the crown, as well as those belonging to private persons, are partly carried on by master-workmen, partly by inrolled boors, partly by vassals, and partly also by free workmen. From these mines Russia obtains annually of gold about 40, and of silver about 1300 pood, amounting, according to the prices in 1789, to the value of 1,729,000 rubles. These metals are brought to St. Petersburg, and there mostly coined, having been previously separated at the imperial office for that purpose, and brought to the perfect standard. Of copper are annually gained about 200,000 pood, estimated in value at about 2,000,000 of rubles. The copper which the crown receives from its mines, as well as from the taxes of private proprietors, is wholly coined. The export of this metal is inconsiderable; as in 1793 it amounted, from all the sea-ports of the empire, only to 187 pood, equal in value to 2910 rubles. Of iron, about 5,000,000 of pood are obtained, the value of which, on account of the fluctuating price, cannot be accurately ascertained. Russia exports every year so great a quantity of this metal, that, next to hemp, it forms the most important article of exportation. In 1793 the export in bar and sort-iron, as well as in cast-iron goods, amounted to 3,033,249 pood, or in value of money by the custom-house books, to 5,204,125 rubles. Lead is found in all the mines, particularly in those of the Nertschinsk and the Altay; but Russia deriving little advantage from it, imported in 1793 at the port of St. Petersburg 36,000 pood, valued at 125,000 rubles. Tin has not as yet been discovered, nor have the semi-metals in general been produced. Russia has ample stores of noble, precious, and durable kinds of stone, which we shall not now record. Turf and coals are found in some parts, the argillaceous earths in great quantities, sulphur sufficient to prevent the necessity of importation, of salts inestimable stores, and of curious petrifications and mineral waters, Russia has a sufficient quantity.

The salt-works of Russia are numerous, rich, and productive. The salt is obtained partly from salt-mines, partly from salt-lakes, in which it crystallizes spontaneously, and partly from salt-springs, by boiling the brine, and evaporation. But notwithstanding its inexhaustible sources of salt,

Russia has not sufficient for the supply of all the provinces without importation. According to the facts above transiently stated, it may be admitted that there is produced annually in the Russian empire, of gold about 40 pood, of silver 1300, of lead 30,000, of copper 200,000, of iron 5,000,000, and of salt 12,000,000; the value of all which in money may be estimated, by the most moderate computation, at 13,000,000 rubles; and if we allow for the advance in the price of mineral products since 1788, and consider their present value, the said sum may be fixed, without exaggeration, at 15,000,000 rubles. According to the lists of exports in 1793, the total capital with which the productive industry of the Russian empire enriched it in that year amounted to 30,823,000 rubles; and this, it is said, is rated too low.

*Manufactures and Trade of the Russian Empire.*—Manufactories of wool, cotton, silk, flax, metals, &c. paper-mills, wax-bleacheries, salt-petre and glass-houses, tapestry and porcelain fabrics, with many similar establishments, belonging partly to the crown and partly to individuals, and especially the working of mines, employ an immense number of people, as well artists as tradesmen, both in town and country. Oils of various kinds, isinglass, tallow, soap, tallow-candles, beer and other liquors, brandy and spirits, vinegar, aqua-fortis and aqua-regia, potash, salt-petre, alum, vitriol, bitter salt, sugar, colours for dye-houses, dyeing, tobacco, paper, paper-hanging, play-cards, printing, sail-cloth and cordage, linen, cotton, silk, gold and silver lace, cloth and stuff, carpet, hat, Russia leather, or red and black yufts, which for colour, smell, and softness, cannot be equalled in any other part of the world, (see YUFTS,) shagreen, wax, cabinet and coach-making, glass, plate-glass, stone-cutting, earthenware and porcelain, feathers, pitch-drawing, charcoal, sulphur, powder, iron in various ways, and for various purposes, copper and brass, cannon, gold and silver, clocks, mammoth's bones, the best of which are found about the rivers Katanga and Indighirka, &c. &c. are the subjects of manufacture, and of the operation of artists in the Russian empire. Siberia produces also a fossil which has the properties of asbestos. It is soaked, like hemp, in water, the threads are then drawn out, of which a linen is made which resists the action of fire.

The commerce of Russia is naturally divided into foreign and domestic: and these again into the maritime commerce on the Baltic and the White sea, on the Euxine and the Caspian; and the commerce by land with Poland, &c. with Persia, with the Kirghises, and with China. The inland commerce is small, and is mostly conducted by shop-keepers and monopolizers; and the chief transport of goods by land is by caravans. The petty merchants carry on their trade by travelling from place to place about the country, and this kind of traffic supports and even enriches many families. Formerly all traffic was confined to the annual fairs; but for a long time every city and town, and many villages, have a regular market, besides the annual fairs. Until about the close of the 15th century, the foreign commerce was trifling, and almost wholly confined to Novgorod. But since the time of Peter the Great, commerce has revived. With the merchants of Russia it is a general practice to be paid half the price before-hand of the inland commodities which they buy up and deliver to foreigners, according to contract, for exportation; but to take foreign goods upon a year's credit. The most considerable maritime commerce is at St. Petersburg and Riga, by way of the Baltic at Archangel, on the Northern ocean, &c., at Taganrok on the Euxine, at Astrachan on the Caspian, and at Kamtschatka on the Eastern ocean. The principal seats of the foreign commerce by land are the Ukraine, whence the

# RUSSIA.

Russian merchants visit the markets of Poland, and the fairs of Germany; Orenburg, where a considerable trade is carried on with several Asiatic nations; and Kiachta in Daouria, where a great mercantile intercourse is held with China.

Hermann states the Russian commerce, in all the ports, which may generally be termed the Baltic trade, as amounting, in 1790, to a sum of 35,750,000 rubles, of which the exports make 21,200,000, and the imports 14,550,000 rubles. From all the ports belonging to Russia in the Euxine or Black sea, the exportation is reckoned at about one million, and the importation at one million and a quarter. The principal articles that find a vent here are, cannon, furs, salted beef, butter, cordage, sail-cloth, caviar, corn, and a variety of Russian manufactures, especially iron, linen, cotton stuffs, &c. The imports are, wine, fruit, coffee, silks, rice, and all kinds of Turkish commodities. The exports over the Caspian are stated to be about 1,200,000, and the imports 1,000,000 rubles. The articles of exportation are nearly the same with those that find purchasers on the Euxine, and in return scarcely any thing is taken but silk. See CASPIAN.

The commerce by land with the Poles, Prussians, &c. is considerable. From these countries Russia takes commodities for about 2,000,000 of rubles, and carries to them for scarcely 500,000. The principal objects of importation are scythes, cloths, linens, hemp, flax, &c. the two last of which products are sent off again from Riga. The commerce by land with Persia passes over Kitzliar and Mofdok, and Russia receives principally, by the same course, silk. The exports amount to about 100,000, and the imports to 200,000 rubles. The commerce with the Kirghises is mostly carried on in the way of barter, and chiefly in the Siberian fortresses of Orenburg, Troitzk, Peterpavlovsk, Yamisheva, Semipalat, and Ustkamenogorsk. Goods to about 1,500,000 of rubles are exported, and imported to the same amount. The Kirghises bring principally horses, horn-cattle, sheep, and very costly sheep-skins, receiving in return from Russia woollen cloths, iron, and a great quantity of household goods and other European commodities. The Chinese commerce is merely a barter, but very considerable. Russia, it is said, has of late years received thence articles for 2,000,000 of rubles, and returned them for nearly as much. The chief articles that come to Russia from China are, tea, silk, and kitaika (nankeen), and of those that are carried thither, the valuable Siberian furs. The total aggregate of the commerce of Russia by land is stated at near 9,800,000 rubles, which gives a balance of about 1,600,000 rubles against the empire.

In 1790 the trade of Petersburg and Riga amounted to as much as the trade of the whole empire in the year 1762, which was then more than twice as much. According to Hermann, the aggregate of the commerce of the empire then amounted to about 50,000,000 of rubles, by which Russia gained near 5,000,000 annually. The returns thus made by the Russian subjects, reckoning exports and imports together, amounted to 15,000,000, among which those commodities are to be understood, which are imported and exported in ships either built or bought in Russia. The subjects have accordingly a share of nearly one-third. The total of the imports and exports of Kiachta may be fairly stated at 4,000,000 of rubles.

In an empire that has 30,000,000 of inhabitants, the *internal* trade must be much more important and valuable than the external commerce. The Siberian commerce, that is, the commerce of the governments of Irkutsk, Kolyvan, Tobolsk, Perm, and Ufa, is of great consequence. All the products of these parts, not consumed in the country,

or not disposed of to China, or to the Kirghises, go by the interior districts and ports of Russia. The major part at least of the heavy commodities is brought almost entirely from the eastern regions of Siberia to St. Petersburg. Most of the return or barter of European commodities against Siberian furs, and against Chinese commodities, is carried on in the town of Irbit, in the government of Perm, where a famous fair is held in the months of January and February. The products carried every year from Siberia to Russia are estimated at 12,000,000 of rubles, which are thus drawn annually by Russia from Siberia; so that Siberia has not unjustly been called the Russian Peru. The interior commerce of the Russian provinces with one another, and their traffic in the ports and frontier places of the empire, are of still greater importance. This kind of lucrative intercourse is facilitated by the many large rivers with which the whole empire abounds. Several considerable fairs that are held in various towns and cities of the empire, contribute in a very great degree to aid the prosecution of traffic. The most considerable of these fairs is that at Makarief, a monastery and city in the government of Nishnei-Novgorod, at which the Siberian and Russian merchants assemble from all parts of the country. Among the trading cities of greatest note, the principal are St. Petersburg, Riga, and Moscow. The latter is the central point at which all the affairs of the interior commerce of the empire flow together and unite, and it contains a numerous and opulent body of mercantile men. Mr. Tooke estimates the aggregate national wealth of Russia in the following manner: 30,000,000 of inhabitants of both sexes, making about 6,000,000 of families, each family consisting of five persons, consume monthly at least 48,000,000, in the whole therefore 576,000,000 of poods of all kinds of meal, grits, &c. each pood, on an average, at 25 kopeeks, makes a sum of

	Rubles.

Salt, 12,000,000 of poods, at 35 kopeeks -	4,200,000
Gold, silver, lead, copper, iron, &c. - - -	8,750,000
Fine and coarse furs - - - - -	5,000,000
Hemp, flax, tobacco, linens, hemp-oil, lin- } seed-oil, &c. - - - - - }	30,000,000
Fire-wood, timber, charcoal, ship-timber, tar, } pitch, &c. - - - - - }	20,000,000
Cattle, leather, wool, milk, pulse, garden } vegetables, &c. - - - - - }	58,050,000
Product of the fisheries - - - - -	15,000,000
Total -	300,000,000

Of this capital, there comes to the annual share of each individual 10 rubles.

By commerce, the annual exports of this capital are,

	Rubles.
In metal wares about - - - - -	3,000,000
In hemp, flax, and articles prepared from } them - - - - - }	10,000,000
In leather, tallow, furs, and all other products } from the animal kingdom - - - - - }	8,000,000
In corn, wood, and other petty articles -	4,500,000
Total -	25,500,000
To this add the transport at - - - - -	2,000,000
which together make out - - - - -	27,500,000

# RUSSIA.

The quantity of money circulating in the empire in 1788, is stated as follows:

	Rubles.
In gold and silver coin - - - -	76,000,000
Copper coin - - - -	54,000,000
Paper money - - - -	100,000,000
<b>Total</b> -	<b>230,000,000</b>

Add together this sum, and the progressive value of the product, and there appears an annual political revenue of 530,000,000, or, to confine ourselves to the lowest, of at least 500,000,000 of rubles. The quantity of specie, from the above-mentioned period, is said to be every year increased:

	Rubles.
By money struck of Siberian gold and silver, } about - - - - - }	1,700,000
By foreign coinage of various sorts - -	1,300,000
By copper money - - - - -	2,000,000
<b>Total</b> -	<b>5,000,000</b>

*Forces of the Russian Empire.*—The Russian army consists partly of regular infantry and cavalry, and partly of irregular troops. To the latter class belong the Kozaks or Cossacks, who answer all the purposes of regular hussars, and have acquired great military reputation. The most serviceable of this class of warriors are divided into those of Ekaterinofslaf and those of the Euxine. It is impossible, from any documents before us, to ascertain the precise number of the Russian military; but from a statement given by Mr. Tooke from the college of war in the year 1791, they amounted to about 600,000 men, of whom might be reckoned at least 500,000 effective soldiers in actual service. Some authors have degraded the value of the Russian soldiers, but from some late memorable exploits their character must have risen in general estimation. A circumstance that distinguishes them is the small pay, on which they are able to subsist. Frederic II. pronounced them to be excellent soldiers. Accordingly it is said, that the Russian soldiers will not fall back one step, while his commander bravely keeps his ground; he contents himself with an extremely little pay, and with very slender diet, and is always cheerful; hungry and thirsty he traverses the heavy sands of the deserts under the load of his accoutrements, without murmur or complaint; executes every command; reckons nothing impossible or too difficult; does every thing that he is ordered to do without shunning any danger; and is inventive of a thousand means for accomplishing his design. What may not be performed with such an army when led on by experienced and valiant generals, in whom they have confidence. Let the foldier but see that he is spared as much as possible, he attaches himself with all his soul to his commander, and performs almost miracles. Well might the empress denominate the Russians an obedient, brave, intrepid, enterprising, and powerful people.

In general, it may be affirmed, that no army in Europe costs so little as the Russian, and that no soldiers in Europe can subsist on so little pay as the Russian. For, what other European soldiers will subsist on an annual pay not amounting to more than seven or eight rubles, or, when in garrison, only half that sum, and the allowance of grits and flour weighed out to him with the utmost nicety?

Concerning the pay of the officers, &c. it must be observed, that the officers of the garrison regiments in the towns of the Baltic, have double the pay of other garrison

regiments; that the officers of all marching regiments have three times the pay of the officers of the regiments in the provinces; and that the private men in the guards have double the pay of those in the marching regiments. A general field-marshal is allowed, *per annum*, 7000 rubles, 200 rations, valued at 1140 rubles, and 16 denshiks or fervants.

	Rubles.	Rations.	Rubles.	Denst.
A general in chief	3600	80 =	456	12
A lieutenant-general	2160	50 =	285	10
A major-general	1800	40 =	228	8
A brigadier -	840	20 =	171	7

In the marching regiments a colonel is allowed yearly 600 rubles, for rations 96 rubles 90 kopeeks, and 6 denshiks or fervants.

	Rubles.		Rub.	Kop.	Denst.
A lieutenant-colonel	360	For rations	62	70	4
A major -	300	—	62	70	3
A captain -	180	—	28	50	2
A lieutenant -	120	—	22	80	1
A second lieutenant	84	—	17	10	1
An ensign -	84	—	17	10	1
A quarter-master } of a regiment }	84	—	22	80	1
An adjutant -	120	—	22	80	1

A private man is allowed yearly 10 rubles 98 kopeeks, besides three barrels of meal, a certain quantity of grist or coarse oatmeal, 24 pounds of salt, and flesh to the value of 72 kopeeks, all which articles are computed at 5 rubles 74 kopeeks. But 6 rubles 35 kopeeks are deducted from the pay of every private man for clothing, medicines, flesh, cartridges, and repairing of fire-locks. His whole clothing from head to foot costs near 12 rubles.

The navy of Russia consists of two fleets, distinct from each other. The creator of the Russian fleet was the emperor Peter I. Before his reign armed vessels, much less ships of war, were not known in Russia; but in consequence of travelling into foreign countries, for the sake of informing himself concerning the best method of building ships, and with a view of introducing it into his empire, he raised a maritime force, and caused a set of regulations to be printed for the establishment of a navy. The admiralty is at Petersburg, with a high admiral at the head of it. According to the regulation of Peter I., the high admiral has the rank and pay of a general field-marshal in the army; an admiral those of a general-in-chief; a vice-admiral those of a lieutenant-general; and a contre-admiral those of a major-general. The captains in the navy were divided by Peter I. into three classes. At present, the captain-commander has the rank of a brigadier in the army; the captain of the first class the rank of a colonel, and the captain of the second class that of a lieutenant-colonel; the captain-lieutenant that of a premier-major; the lieutenant that of a captain in the army, and the midshipman that of a lieutenant. The pay of the high admiral *per annum* is 7000 rubles; that of an admiral, 3600; of a vice-admiral, 2160; of a contre-admiral, 1800; of a captain-commander, 840; of a lieutenant 200, and of a midshipman 120 rubles. Officers are allowed denshiks or fervants, *viz.* a lieutenant two, and the rest in proportion. When they are at sea, the officers are allowed table-money, *viz.* in the Baltic, each officer monthly has seven rubles, and the captain somewhat more. On long voyages this allowance is increased. The sailors are divided into two classes: to the first belong the experienced, at 18 rubles *per annum* each; but those of the second class have only 12. Moreover, they are fed while at sea;

sea; but when on shore, each receives his ordinary provision, as in the land service. To a ship of 100 guns the crew is usually reckoned at 1000 men.

Russia had formerly no more than two dock-yards, those of Petersburg and Archangel, to which have been added those of Kherfon, Cronitadt, and Taurida. At Petersburg and Cronitadt the men of war are constructed of oak, transported thither at a great expence from Kazan. At Archangel the ships are built of the wood of the larch-tree.

*Revenues of the Russian Empire.*—Mr. Coxe estimates the national revenue of Russia at 41,830,910 rubles, which is below the just amount. Mr. Tooke professes to give a more accurate statement: and he begins with enumerating the sources from which the national revenue is derived. The first of these sources is the “head-money,” paid only by male heads, including babes and old men, and supposing 12,000,000 of taxable persons, and averaging them at 72 kopeeks each, the amount will be very considerable. The second source is the “tax upon the capital of merchants,” or, as it is sometimes called, the *per centage*. Every one pays yearly one *per cent*, in return for which he and his children are exempt from the poll-tax. The third source of revenue is the “domain lands,” the income of which is very various. 4. The “sea-duties,” which are liable to great fluctuations. 5. The “land-tolls.” 6. The duties on “law-proceedings,” commonly called “*poschlin*,” to which may be referred the passport money. 7. “Stamped-paper,” which brings in a considerable sum *per annum*. 8. The duty on the “sale of immoveable property,” including not only houses and lands but also vassals; fixed by the late empress in 1787 at five *per cent*. 9. The “kabaks,” or tipping-houses, or the sale of corn spirits. 10. The “salt-trade.” 11. The “mines.” 12. The “mint.” 13. “Natural products.” 14. The share of “excise and recognition duties” in towns. 15. The “posts.” 16. All kinds of “rent” for places, shops, mills, parcels of ground, bee-hives in forests, bathing-houses, fisheries, public inns, &c. 17. “Recruit money” from merchants, from which foreign merchants are exempt. 18. Various “pecuniary penalties.” The amount of the receipts from the several towns is upwards of 46,000,000 of rubles, which it has been thought may be rated at 48,000,000.

*Coins, Measures, and Weights of the Russian Empire.*—We are informed by Mr. Tooke (*ubi infra*), that previous to the 10th century neither foreign nor domestic coin was known in Russia; but that instead of it, small pieces of marten and squirrel skins, stamped, were the only currency. From that period frequent mention is made in the chronicles of Grecian and other sorts of money. It is said by some persons, that the first coins were introduced by the Tartars into Russia, and that the Russian word for money, “*denghi*,” is derived from the Tartarian term “*tanga*,” which signifies a token; but, when coins were impressed with the arms of Moscow, *viz.* a St. George and his spear, the name “*kopeeka*” arose from *kopæ*, or *kopeitso*, a spear. Towards the middle of the 16th century, though coins had been struck in several places before, the czar Ivan Vassilievitch instituted the first regular coinage, set up a mint at Moscow, and caused three rubles to be struck out of one “*grivenka*,” denoting probably a certain weight of silver. However, at this time, and long afterwards, the ruble was only an imaginary coin. The first actual rubles were struck during the reign of czar Alexey Mikhailovitch, in the year 1654, though history makes mention of the ruble about the year 1317. The first ruble of 1654 is still extant, and it is easily discernible to have been previously a Spanish cross-dollar; Russian rubles having been recoined from dollars. A foreign dollar then passed for 50 kopeeks. But afterwards, in consequence of

the war with Poland, the coin suffered a diminution; and for some time, kopeeks and altines were struck of copper. The intrinsic value, however, of the ruble remained unaltered at 100 kopeeks. Various alterations were made in the coinage by Peter I. By an edict of 1724, he ordered that no more silver kopeeks should be coined, and in lieu of them he caused to be struck one and two-kopeek pieces of copper, having on one side the St. George, and on the other within the initial of the emperor’s name П, the value of the coin. All mints were abolished except those at Moscow; and in process of time a mint was set up at St. Petersburg, which is at present the only one where gold and silver coins are struck. Although the mint of Moscow still exists, it is confined to the coinage of copper money. At this time Russia has one mint for silver and six for copper coin.

After the battle of Pultava, Peter caused to be coined pieces called *sun-rubles*, now very scarce, having on the reverse a sun in the centre, and in the area the initial in Russ П. Besides the ruble, there were coined at the same time half and quarter-rubles (*poltiniki* and *polpoltiniki*, or *poltins* and *polpoltins*), bearing his likenesses and the imperial eagle. The *grievens*, or tenth part of a ruble, had 10 dots, with the inscription “*Grievnik*” on one side, and the eagle on the other. The *altins*, or three kopeeks (*copeeks*), had on one side the eagle, and on the other the date of the year and the word “*Altinik*.” These were all the silver coins under Peter I. The empress Elizabeth for a short time caused five-kopeek pieces to be coined, which have long since ceased. The gold coins in Russia have been always struck in larger sorts than those of silver. Nevertheless most of the gold coins, of ancient times, still subsisting, consist of very small sorts. There are some that are called “*golden kopeeks*.” A Russian ducat was formerly equal to two rubles silver, whence probably arose the denomination of golden ruble, as well as the quarter-ruble, now shewn as curiosities. Under Peter I. the gold coins were either two-ruble pieces, with the apostle Andrew on the reverse, which are very rare; or ducats with a Latin inscription. On one side is the bust of Peter with a crown of laurels, on the other the Russian imperial eagle, with the St. George on its breast. Both sides have round them “*Petrus Alexii I. D. G. Russ. Imp. M. Dux Moscovix 1716*.” The empress Elizabeth first caused imperials, half-imperials, golden rubles, and half-rubles, to be struck. At the accession of Peter I. the copper coins were half-kopeeks (*denufchka* or *denga*), kopeeks, and five-kopeek pieces. On the first, stands on one side “*Denga*,” and on the other 1706. The kopeeks have on one side the St. George, and on the other “*Kopeika*.” The five-kopeek pieces have undergone several alterations. The copper five-kopeek pieces that had been struck by Elizabeth were fixed by Peter III. at 10, but Catharine II. reduced them again to five kopeeks. For the accommodation of the provinces of Esthonia and Livonia, the empress Elizabeth, in 1757, caused to be struck the *livoneses* of whole, half, and quarter pieces; the whole piece being in value 96 kopeeks; but the coinage of these soon ceased.

In Russia, accounts are kept in rubles of 100 kopeeks or *copeeks*. The ruble is divided into 10 *grievens*, 33 *altins*, or 50 *groschen*; and the kopeek or *copeek* is divided into 2 *denufchkas*, or 4 *polufchkas*. The coins now in circulation are, of gold, the imperial, and half-imperial of 10 and 5 rubles; double and single ducats, which were formerly worth  $4\frac{1}{2}$  rubles and  $2\frac{1}{4}$  rubles; but their value was raised, in 1764, that of the double ducat to 5 rubles 60 *copeeks*, and the single to 2 rubles 80 *copeeks*. The silver coins are, rubles of 100 *copeeks*; *poltins*, or half-rubles, of

## RUSSIA.

50 copecks; polpolims, or quarter-rubles, of 25 copecks; double and single grieven, of 20 and 10 copecks; and pieces of 5 altins or 15 copecks; payte-copecks of 5 copecks each, and altins of three copecks, the two latter of which are now nearly out of circulation. The copper coins are pieces of 10 copecks, called grieven or grievnik, of 5 copecks or pataki, which are the most common, of two copecks or grosch, of 1 kopeck; also denuschkas or half-copecks, and poluschkas or quarter-copecks. The following table shews their mutual relation as to value:

Ruble.	Grievnik.	Altine.	Copecks.	Denuschkas.	Poluschkas.
1	10	33 $\frac{1}{2}$	100	200	400
	1	3 $\frac{1}{2}$	10	20	40
		1	3	6	12
			1	2	4
				1	2

Dutch ducats are worth 2 $\frac{1}{2}$  rubles, more or less; Dutch and Danish rixdollars pass for 1 ruble 40 copecks; or 14 rixdollars, weighing a Russian pound, (1 lb. 1 oz. 3 dwt. 2 gr. troy,) are worth 19 rubles 6 copecks.

The fineness both of gold and silver is expressed in solotniks, the pound or other weight being divided into 96 such parts. The solotnik is also the  $\frac{1}{96}$ th part of a Russian pound weight. By the ukase, or edict, of 1763, the imperial was to weigh 3 $\frac{1}{4}$  solotniks, the half-imperial 1 $\frac{3}{4}$  solotniks; and the gold to be 88 solotniks, or 22 carats fine. Also, 118 ducats were to weigh a Russian pound, 93 solotniks fine, or 23 $\frac{1}{2}$  carats. By the same edict, silver of 72 solotniks, or 9 oz. fine, was coined into rubles and half-rubles, at the rate of 17 rubles 6 $\frac{1}{2}$  copecks *per lb.*; into quarter-rubles and 20-copeck pieces, at the rate of 17 rubles 15 $\frac{3}{8}$  copecks *per lb.*; and into grievens and 15-copeck pieces, at the rate of 17 rubles 25 $\frac{5}{8}$  copecks *per lb.* Copper was coined at the rate of 16 rubles *per pood* of 40 Russian pounds. New regulations were established by an edict of the emperor Alexander, in 1801; according to which, 22 $\frac{1}{2}$  rubles are to contain a Russian pound of fine silver; and they are to be 83 $\frac{1}{2}$  solotniks (11 oz. 8 dwt.) fine; and thus each ruble should weigh 320 $\frac{1}{2}$  English grains, and contain 277 $\frac{1}{2}$  grains of fine silver. It was also declared, that no gold coin should hereafter be struck in Russia, except the imperial and half-imperial, the standard of which was raised to 94 $\frac{1}{2}$  solotniks, or 23 $\frac{3}{4}$  carats; and the weight of the imperial reduced to 2 $\frac{1}{2}$  solotniks, or 188 $\frac{1}{2}$  English grains; by which the value is nearly the same as before.

According to these mint regulations,

	£	s.	d.	
The imperial is worth	1	12	9 $\frac{1}{2}$	} valued in English gold.
The ducat - - - -	0	9	1	
The ruble of 1763 - -	0	3	3	} valued in English silver.
The ruble of 1801 - -	0	3	2 $\frac{1}{2}$	

The following is the report of an assay lately made on a number of rubles at the London mint, by order of the Bank of England. Rubles of 1763, weight from 14 dwt. 21 gr. to 15 dwt. 20 gr.; average 15 dwt. 8 $\frac{1}{2}$  gr.; fineness 44 dwt. worse than English, that is, 8 oz. 18 dwt. Rubles of 1801, weight from 13 dwt. 2 gr. to 13 dwt. 12 gr.; average 13 dwt. 7 gr.; fineness 14 dwt. worse than English, that is, 10 oz. 8 dwt. Hence we have the value of the old ruble, 3s. 2d. sterling; and of the new, 3s. 2 $\frac{1}{2}$ d.

Besides the hard coin, "paper money" constitutes the chief circulating medium or money of Russia, under the denomination of "bank-assignments." Until the year 1787, these notes of 100, 50, and 25 rubles in circulation were estimated at the amount of 50 millions of rubles. They

were so readily taken through the whole empire, instead of copper money, that, in many places, 1, 2, and as far as 5 *per cent.* agio must be given to get paper money for copper. In 1787 the old notes were liquidated, and a fresh issue was made to the amount of 100 millions. They are at a *per cent.* of 100, 50, 25, 10, and 5 rubles. By the ukase of August 3, 1788, it was ordered, that there should be never more than 100 millions in circulation. It was customary to convert them into copper money on demand at the assignation-banks; but they fluctuate considerably in value, and with respect to gold and silver they are mostly at a discount; and even on copper there is sometimes an agio against them, as they are not always paid off in this metal, when the sum is considerable. The ruble of exchange is subject to a similar depreciation. In 1770 this ruble and the paper ruble were at par with the silver ruble; in 1790 they were 20 *per cent.* worse; in 1799 the paper ruble was 60 *per cent.* below par, and the ruble of exchange 50 *per cent.*; in 1803 the paper ruble was 20 *per cent.*, and the ruble of exchange 10 *per cent.* below par; and in 1808 they were 100 *per cent.* worse, that is, 1 silver ruble was worth 2 rubles of exchange, or 2 of bank paper.

Bills of exchange are paid in copper, or bank notes; but this chiefly regards inland bills, as foreign merchants scarcely ever draw on Russia. The commercial debts here are usually settled by drawing and remitting bills on foreign countries.

Peterburg, Archangel, Moscow, &c. draw on the following places, and give Amsterdam 1 ruble for 37 stivers current, more or less, at 65 days' date; Hamburg, 1 ruble for 34 schillings or fols banco, more or less, at 65 days' date; London, 1 ruble for 38d. sterling, more or less, at 3 months' date.

The ruble here mentioned is not the silver ruble, but the ruble of exchange, which, as we have just stated, is subject to great fluctuations.

Bills drawn in Russia, payable after date, are allowed 10 days' grace; but if payable at sight, 3 days only; but bills payable at so many days after sight are not allowed any days of grace.

During the reign of the empress Catharine, three different banks were established at Peterburg, *viz.* the Loan-bank, the Assignation-bank, and the Loan-bank for the nobility and towns; and during the reign of the emperor Paul, the Aid-bank and Discount-office were established.

The "Loan-bank, or Lombard," lends money on gold, silver, jewels, &c. A year's interest is taken in advance, which, according to the legal rate, is 5 *per cent.* No interest is paid for money drawn out, on giving two days' notice; but if a declaration be made, that the money will be left there a year, and that a notice of three months shall be given of the intention to draw it out, the legal interest is allowed, payable in the same kind of money in which the deposit was made. The property of this bank belongs to the Foundling-hospital at Peterburg.

The "Assignation-bank" was opened in Peterburg and Moscow in the year 1770, and branches of it have been extended to Yaroslaf, Smolensk, Veliki-Usting, Altrachan, Nishnei-Novgorod, Visehnevolutschok, Novgorod, Pfcove, Tver, Nefchna, Kief, Kursk, Kharkof, Tambof, Orel, Tula, Kazan, Kherfon, Archangel, Riga, and Revel. This bank issues notes for 5, 10, 25, 50, and 100 rubles. In 1786 it was converted into an imperial establishment, when all the old notes were called in, and exchanged for new ones. It is engaged that these notes are to be reimbursed on demand in copper money, and that the total amount should not exceed 100 millions of rubles; but the number

number now in circulation is supposed to be greatly beyond this limitation.

The "Loan-bank for the nobility and towns" was established in 1786, for the purpose of advancing money to the nobility on landed property or on male peasants, and to the cities or towns on the security of stone and brick houses. The annual interest charged is 5 per cent.; besides which,  $\frac{3}{4}$  per cent. must be paid annually, towards diminishing the capital, or redeeming part of the mortgage, till the whole be repaid. The loans are made in assignation-notes. This bank is also empowered to insure houses, buildings, and other property, on which it has advanced money, at the annual premium of  $1\frac{1}{2}$  per cent. It is also allowed to coin money of gold, silver, and copper, according to the mint regulations; and it has the liberty of discounting bills at  $\frac{1}{2}$  per cent. per month.

The "Aid-bank" was established in 1797, for affording relief to noblemen, whose estates are mortgaged, or burdened with debts; and also for advancing money to those who wish to improve their estates, to establish works or manufactures, &c. The property is valued according to the number of male peasants on the estates, who, in different provinces, are valued at 40, 50, 65, and 75 rubles per man. The money is advanced in tickets secured on the estates, which are transferrable, and are to be taken as legal money in all the departments of government. These tickets may remain in circulation for 25 years, reckoning from the time of opening the bank. The annual interest is 6 per cent. for the first five years, and 5 per cent. for the following years; and a part of the debt is to be discharged annually, till the whole be repaid, which must be done within 25 years from the opening of the bank. If the interest is not regularly paid, a fine is imposed, which increases at the rate of 1 per cent. per month, till the third month; and if the interest is not then paid, together with part of the capital, the management of the estate is taken from the owner, and given to noblemen who live nearest to it, and they are to receive the produce, and remit it to the bank, till the debt is entirely paid. The payment must be made in copper money, or notes of the Assignation-bank.

The "Discount-office" was established in 1797, for advancing money on bills and on goods of Russian produce, and also for insuring the goods on which such advances have been made. The holder of the bills or owner of the goods must be a Russian subject; but money is advanced to foreigners, and all sorts of people, on gold and silver.

The Russian weights are as follow: the berquet or berkwitz = 10 poods; the pood = 40 lb.; the lb. = 32 loths or lotes; and the loth = 3 solotniks. The Russian lb. = 28 loths, Cologne weight, or 6314 troy grains; so that 500 lb. Russian = 451 lb. avoirdupois. Among merchants, the ordinary computation is, that 36 lb. avoirdupois = the Russian pood, and that 63 poods = 1 ton avoirdupois. Hemp, flax, and cotton, are sold by the berquet; copper, iron, cordage, horse-hair and tails, linseed and hempseed oil, singlafs, morocco leather, potash, wax, bristles, and tobacco, are sold by the pood.

The measures of Russia are, for corn, the chetwert or cool = 2 ofmins = 4 pajacks = 8 chetwericks = 64 garnitzky. A cool of flour = 9 poods, and a sack = 5 poods. The chetwerick is  $13\frac{1}{2}$  English inches in diameter, and  $11\frac{1}{2}$  in depth; so that it measures 1555.92 cubic inches, and contains  $5\frac{7}{8}$  Winchester gallons nearly. In business the computation is, that 100 chetwerts = 72 quarters, and 1 chetwert =  $5\frac{3}{4}$  bushels, Winchester measure. For wine, the cask, farokowoi, or pipe, contains 40 vedros; the vedro = 8 ofmuchki or krushkas, and the krushka = 11

tfcharkays or cups. In Peterburg the vedro contains 621 French, or 752 English cubic inches: hence 1 vedro =  $3\frac{1}{4}$  English wine gallons; and 3 krushkas = 1 English ale gallon. The long measures are an arsheen or arshine, which is divided into 16 werfchocks or werfhoks = 28 English inches; so that 9 arsheens = 7 English yards, and 4 werfchocks = 7 English inches; a saze, fashe, fajene, or fathom = 3 arsheens, or 7 English feet; a werst, werst, or Russian mile = 500 fajenes = 1500 arsheens = 3500 English feet: 20 wersts = 3 German miles, and 264 wersts = 175 English miles; so that a werst is nearly two-thirds of an English mile; and a degree of the meridian is reckoned to be about 104 wersts. The Russian foot is 155 French lines =  $13\frac{1}{4}$  English inches; and the Moscow foot =  $148\frac{1}{2}$  French lines =  $13\frac{1}{4}$  English inches; but the English foot, as well as the Rhineland foot, is generally used in Peterburg. The superficial measure, called dessjetina or desjetine, contains 2400 Russian square fathoms, or 21,600 square arsheens = 13,066 $\frac{2}{3}$  English square yards, or 2 acres 2 roods 32 perches: hence 10 dessjetinas correspond to 27 English acres nearly.

In Russia the Julian calendar, or old style, is still retained, which (since the year 1800) is 12 days later than the new style; so that a Russian bill, dated the first day of any month, must be reckoned from the 13th day of the same month in England, and in every other place where the Gregorian calendar, or new style, is used.

Having availed ourselves of the materials which are furnished by Mr. Coxe, in his "Travels" and "Russian Discoveries," and by Mr. Tooke in his comprehensive and very interesting "View of the Russian Empire," in the compilation of this article, we shall close it with observing, that the immense territory of the Russian empire naturally forms itself into two great divisions, by the vast Ural chain of mountains, that intersect it from north to south; but these divisions are very unequal and dissimilar, both as to dimension and quality. That on the westward is *Proper* or *European* Russia; and that lying to the east side, *Asiatic* Russia, or *Siberia*.

*European* Russia extends, by the final partition of Poland, from the river Dneister to the Uralian mountains, the grand chain which, as we have just said, divides Europe from Asia; in length about 1600 miles, and in breadth above 1000 English miles. The extent is computed at about 1,200,000 square miles. For a further account of *Asiatic* Russia, see *SIBERIA*.

*Russia Company.* See *COMPANY*.

*Russian Music, in the Church.* See *GREEK Church*.

*Russian Secular Music.* The only instruments known in Russia till the time of Peter the Great, were such as the peasants still use in the provinces, which are described in the Gotha Almanac, and in Guthrie's Dissertations, with drawings. Peter had at first only such military instruments as he had seen in Germany. But the first good music that was heard in Russia, was brought thither by duke Charles Frederick of Holstein-Gottorp, at Petersburg. This prince, destined to marry the princess Anne Petrowna, daughter of Peter, had a complete band, or chapel, as the Germans call it, in his suite, composed of twelve good German musicians: the concerts by this band were new and acceptable to all the great Russian nobility, who had never heard any other music than that of the natives, which was coarse and barbarous. The emperor himself used to frequent these concerts, and established two regular performances in his palace each week, employing the German musicians to teach the boys about the court, and in the army.

All the successors of Peter have followed his example as a model in this instance, as in all others.

The empress Anne, the niece and successor of the great Peter in 1730, who died in 1740, early in her reign first regaled Petersburg with an Italian opera composed by Araja, a native of Italy, of some eminence, whom she appointed her maestro di cappella; and who likewise composed intermezzi to Italian words, and in the musical style of his country. Concerts twice a-week, which had been established at court, have been continued ever since. All the grandees of Russia imitated this example, had private concerts in their mansions, and many of them became dilettante performers themselves in a high form of excellence.

The empress Elizabeth, daughter of Peter, began her reign in 1741, by a revolution which set aside the czar Ivan as incapable of reigning. She had been affianced, in 1747, to the duke of Holstein-Gottorp; but that prince dying before the marriage took place, she passed the rest of her days in a single state. This princess, on whom nature had bestowed a nice discriminating ear, with a passion for music and all the fine arts, by her patronage caused them to flourish in her dominions, in a way superior to most of the other states of Europe. She built an opera-house at Moscow, capable of containing 5000 people. At her coronation, "La Clemenza di Tito," written by Metastasio, and set by Hasse, was performed by the best Italian singers of the time; and a prologue to this drama, entitled "La Russia afflitta e consolata," was set by Araja, maestro di cappella to the court of Petersburg. Soon after this, Petersburg first heard an opera in the Slavonian language, set likewise by Araja.

Such was the progress which music had made in Russia, when Peter Federowitz, consort to the empress Catharine, was called to the throne as presumptive heir. The passion which this prince had for music contributed considerably to its further advancement into favour in his dominions. He performed himself on the violin sufficiently to bear a part in a symphony. If he now and then played a wrong note, or missed a difficult passage, the Italian musicians were too polite to notice it; on the contrary, they persuaded his imperial majesty that he had a particular talent for music, and that his performance on the violin was perfect. Music became his favourite, and almost sole amusement, even to a degree of enthusiasm. He became also a great connoisseur in violins; and, in a short time, purchased a great collection of those made by the most celebrated artists, particularly those of Cremona, by Amati, Stradivarius, Guarnerio, &c. and by Steiner and Albani, Germans. He was never more happy than when at the head of his band in his concerts. He intended assembling at his court all the great musicians in Europe, and he would doubtless have succeeded, if his reign had been more durable; but aiming at more important revolutions in his state (which, happily for his country, were stopt), a termination was put at once to his musical and political projects.

Catharine II. mounted the throne, attended not only by all the sciences and fine arts, but by the genius of legislators and victory. The state, the church, public order, industry, commerce, maritime force, and the state of her army, had her first attention.

After having provided for the safety and power of her empire, she attended to its embellishment by means of the fine arts; and erected a temple to painting, sculpture, architecture, and formed an imperial academy of sciences and beaux arts at Petersburg.

After this latter establishment, which has since become so illustrious, she turned her thoughts to music, and called to

her court from Venice the celebrated Baldassar Galuppi, detto Il Buranello, the most fertile and spirited composer of his time. His "Didone abbandonata," in which the Gabrielle performed the part of Dido, had such prodigious success, that, after the first representation, the empress, with her own hands, presented the composer with a magnificent box filled with pieces of gold: telling him that "the unfortunate Dido, when she expired, bequeathed it as a legacy to the illustrious Buranello."

Those who recollect the turn which this princess gave to her munificence in the purchase of Diderot's library, will be less surpris'd at her liberality to Buranello. Diderot, in his latter years, being constrained to offer his library to sale, unsuccessfully, to the principal sovereigns in Europe, in order to enable him to educate his only daughter, when his wish was communicated to the empress Catharine, she said, "she would willingly purchase his library of him at his own price, upon condition that he would be so obliging as to take care of it as long as he lived; and in order to improve it, and to keep pace with the times, she hoped that he would take the trouble to lay out for her 2000 rubles a-year in the purchase of new books."

Buranello was succeeded at Petersburg by Traetta, an excellent composer; and the compositions of these great masters, sung by the finest voices of Italy, and accompanied by the best instrumental performers with which the orchestra could be supplied, together with the taste and magnificence of the decorations, and the splendour of the dances, rendered the opera at Petersburg the most brilliant and renowned spectacle in Europe.

When the empress and her son, the grand duke, had so happily recovered of the small-pox, by the inoculation of baron Dimsdale, the agreeable French comic opera of "Annette and Lubin" was performed by the principal nobility of the court; however, too good a taste in singing and in dramatic music was formed at Petersburg now, for the vocal performers of France to captivate much, even with the compositions of Duni, Montigni, Philidor, and Gretry, which were tried for one season.

It is to sacred music that the lyric theatre at Petersburg is obliged for the great effects of its chorusses. In the opera of "Ifigenia in Tauride," set by Galuppi, he was allowed to make use of the choral singers of the imperial chapel. Of which permission that great master availing himself, composed chorusses for ten choirs, in four parts each, which had a most surpris'ing effect. See **CHACE**.

After the period described by the Gotha Almanac for 1772, the opera of Petersburg had Paisiello and Sarti to compose. Paisiello, after three years residence in Russia, where his compositions and personal merits were perfectly understood, and treated with great admiration and regard, was succeeded by Sarti, who went to Petersburg in 1784, for three years, but remained in Russia till 1790; during which time he established a concert spirituel, or oratorio, for which he composed music *à cappella*, in which he introduced instruments which are not allowed in the Greek church. He likewise composed a Te Deum for the victory obtained over the Turks by the Russians at Oczakow, and established a conservatorio for the education of young musicians in the Neapolitan manner, of which he was appointed director. With his opera of "Armida" the empress was so pleas'd, that she gave him a golden vase, and a ring of great value. See **SARTI**.

Music is still patronized in Russia; concerts and operas are supported in the usual magnificent manner (1805); and the Italian taste, besides its prevalence at the opera and court

concerts to Italian words, is propagated in the church and provinces by national composers, who had been sent to Italy by the empress Catharine to study composition, and who, when they returned, set hymns, motets, and songs in the Slavonian language, which is said to be nearly as soft and capable of receiving melody as the Italian. Palcha, Lolli, Giornovich, Bortnianiki, Dietz, &c. contributed to refine instrumental music in Russia.

**RUSSING**, in *Geography*, a town of Austria; 6 miles E. of St. Polten.

**RUSSWEIL**, a town of Switzerland, in the canton of Lucerne; 6 miles W. of Lucerne.

**RUST**, **FREDERIC WILLIAM**, in *Biography*, born in 1739, music-director at Dessau. His first instrument was the violin, then the harpsichord; but he seems to have played and written for all kinds of instruments, though chiefly for the harpsichord. He published at Leipzig six sonatas for that instrument, and twenty-four variations to a German song, at Dessau, 1782; with many detached songs and odes for periodical works.

**RUST**, in *Geography*, a town of Hungary, the inhabitants of which carry on a considerable trade in wine, made nearly as strong as Tokay; 4 miles E.N.E. of Edenburg.—Also, a small island in the North sea, about 60 miles from the coast of Norway. N. lat. 67° 5'.

**RUST**, in *Rural Economy*, a distemper incident to corn, and generally called mildew. (See **MILDEW**. See also **BLIGHT**, and **SMUT**.) The ancients generally thought that it came from heaven, being ignorant of its true cause. Virgil gives this up as an incurable distemper, and tells the farmer, that if his corn is blighted he must live upon acorns, not supposing that any remedy could be devised for such a distemper. These people in general, having no true knowledge of the theory of husbandry, had recourse to magic, and used what they thought spells and enchantments on all occasions. Cato, Varro, and even Columella, are full of these ridiculous devices. A better knowledge in the real nature of husbandry has taught us to understand this matter in a very different manner, and to apply more efficacious remedies to it.

Wheat is blighted at seasons, first in the blossom, and then its generation is prevented, many of the husks being empty in the ear, and the rudiments of the grains not impregnated; secondly, wheat is blighted when the grains are brought to maturity; and in this case they become light, and are of little value for making of bread, having scarcely any flour in them.

Under this term of rust may, perhaps, most properly be arranged, and included, that sort of destructive affection of grain, which is caused by the funguses and parasitical plants, which fix themselves on, and attach themselves to, the stems or other parts of it, so as to diminish, intercept, or destroy its nutritive properties and qualities. The injury done in this way is often more dreadful than that from any of the other causes, as whole fields have been known to be utterly destroyed, so as not to contain a single grain of wheat in the ear, and, at the same time, the straw rendered totally unfit for fodder, as being little better than a *caput mortuum*, possessing neither strength nor substance in it. The evidence of different places fully confirm the existence of fungi, as injurious in this manner; as from some it is stated, that, as the wet weather continued, the rust or fungus made a rapid progress from the ear downwards, until, in many instances, it covered the stem from the ear, as far as it was unsheathed. From others it is said, that the rust or fungus prevented those grains which the maggot had not destroyed from being perfected, in a greater or less degree. From still others it

is asserted, that these parasitical plants multiplied so much upon the straw, and on the hulk and chaff of the ears, that, in many cases, whole fields put on an universal blackened, rusty appearance. From different other persons, various other circumstances of this nature are also related to be met with.

The best means of preventing and removing affections of this nature in this sort of grain crop, are supposed to be those of cultivating only the sorts of wheat which are the hardiest in point of quality, and the least liable to disease; the sowing of the wheat earlier than usual in the season; the introduction of earlier varieties of it; the giving of a sufficient quantity of seed; the draining of the land where it is inclined to be wet; the rolling and treading of the land by live-stock immediately after sowing; the use of sowing different sorts of saline substances as a manure; the proper regulation and improvement of the course of crops; the change of seed, by bringing it fresh from other countries; the extirpation of the diseased stems, stalks, or blades early in the season; and the instantly cutting down of the crop when it is decidedly affected. See *ROTATION of Crops*, *SALINE Manure*, *TREADING*, and *WHEAT*.

It is supposed, that, by means of one or other of these methods, when properly improved and applied by ingenious naturalists and farmers, there can be no doubt but that this, as well as the other diseases in wheat crops, may, in a great measure, be either wholly remedied, or their effects be so far reduced as to be of little national consequence. Sir John Sinclair's Inquiry into the Blight, Rust, and Mildew in Wheat.

The rust or mildew also attacks, and is highly injurious to many sorts of garden vegetables as well as fruit-trees, such as those of late peas, &c. and peach-trees, &c.

On the supposition of the disease, in these cases, arising from the seeds of fungi, and to be promoted immediately afterwards, and in continuance, by the want of a sufficient supply of moisture from the soil or ground, with an excess of humidity in the air, particularly when the plants are exposed to a temperature below that to which they have been accustomed; the president of the Horticultural Society of London was led to pursue the following mode of cultivation with the late autumnal crops of the pea, by which the table may be as abundantly supplied during the month of September and that which succeeds it, as in those of June and July; and the plants be nearly as free from the disease. The ground is first dug up in the usual manner, and the spaces which are to be occupied by the future rows of peas then well soaked with water. After which, the mould upon each side is collected together, so as to form ridges seven or eight inches above the previous level of the surface of the ground, which are also well watered. The seed-peas are then sown, in single rows, along the tops of the ridges. The plants quickly shew themselves above the surface of the land, and grow with much vigour, on account of the great depth of stirred mould, and the abundant moisture. There is water given in rather a profuse manner, once in the course of every week or nine days, even when the weather proves showery, but if the ground should be thoroughly drenched with the water of the autumnal rains, there will be no further trouble necessary. The plants, under this mode of management, continue perfectly green and luxuriant, until their blossoms and young seed-vessels become destroyed by the frosts; and their produce will retain its proper flavour, which is constantly destroyed by this disease.

The pea, which has constantly been cultivated in this intention and manner, is a very large kind, the seeds of which

are greatly shrivelled, and grow very high: it is now become common in the seed shops of the metropolis under the title of knight's pea. This variety is preferred on account of its more saccharine quality, and the retention of its flavour more perfectly in the autumnal season; however, it is not improbable but that any other late tall-growing variety may succeed equally well. It is the practice to sow a small quantity every ten days until about midsummer, which afford good supplies for the table until the end of October, though the severe frosts, which sometimes happen in the early part of that month, prove destructive of the more late crops.

The same, or similar means, it is supposed, may be equally effectual in preventing this disease in the peach-tree. As it is found, that when the roots of it, which strike to the greatest depth in the soil, and which are consequently the best suited to supply the tree with moisture during the summer, are destroyed by a hurtful under soil, or by an excess of moisture in the winter season, the disease, on many varieties of the peach-tree, becomes extremely formidable. But that where, on the contrary, a deep, fertile, dry loam permits the roots to extend to their proper depth; and where the situation is not so low as to be much infested with fogs, little of this disease is met with: also in a forcing-house it has been found equally easy, by appropriate management, to introduce or prevent the appearance of it. When the mould has been kept very dry, and the air in the house damp and unchanged, the plants have soon become diseased; but when the mould has been regularly, and rather abundantly watered, not a single vestige of the disease has shewn itself.

**RUST**, in *Gardening*, a disease of the blight or mildew kind, which affects many sorts of crops, as well as some fruit-trees. All the later pea, bean, kidney-bean, and several other similar sorts of crops, are liable to be attacked, and greatly injured, or wholly destroyed in this way. Some kinds of the peach and other sorts of the finer fruit-trees are also much exposed to its ravages and destructive effects. See the preceding article.

**RUST of a metal**, the flowers or calx thereof, procured by corroding and dissolving its superficial parts by some menstruous fluid: or the earth of the metal decomposed by the action of a proper menstruum.

Water is the great instrument or agent in producing rust; the air apparently rusts bodies, but it is only in virtue of the water it contains.

Hence, in a dry air, metals remain a long time without contracting rust; and hence oils, and other fatty bodies, secure metals from rust, or from being oxydated; water being no menstruum to oil, &c. and therefore not able to make its way through it. See **IRON**.

All metals are liable to rust; even gold itself, though generally held incapable of it, grows rusty, if exposed to the fumes of sea-salt.

The reason why gold is so rarely found to rust is, that sea-salt, which is the only salt that will prey upon it, is of a very fixed nature; and therefore little of its effluvia, or exhalations, are found floating in the air.

Rust is usually supposed to be a corruption of the metal, but without much foundation: it is the very metal itself, only under another form; and accordingly we find, that rust of copper may again be turned into copper.

The rust of copper, called *arugo*, makes what we call *verdigris*. Cerufs is made of lead converted into rust by vinegar. Iron, in time, turns wholly into rust, unless preserved from the air by paint or varnish.

Citizen Conté has adopted a method, which he finds effectual, for preventing the oxydation of iron and steel;

or, in popular terms, to prevent iron and steel from rusting. It consists in mixing with fat oil varnish, at least half, or at most four-fifths of its quantity of highly rectified spirits of turpentine. This varnish must be lightly and evenly applied with a sponge; after which the article is left to dry in some situation not exposed to dust. He affirms that articles thus varnished retain their metallic lustre, and do not contract any spots of rust. This varnish may also be applied to copper, of which it preserves the polish, and heightens the colour. It may be employed with particular advantage to preserve philosophical instruments from any change, in experiments where, by being placed in contact with water, they are subject to lose that polish and precision of form, which constituted part of their value. *Nicholson's Journal*, vol. vi. p. 142.

Plumbago protects iron from rust, and on that account is rubbed on various ornamental cast-iron works, such as the fronts of grates, &c.

**RUSTAN**, in *Geography*, a town of Persia, in the province of Schirvan; 14 miles N. of Derbend.

**RUSTANGUNGE**, a town of Hindoostan, in Bahar; 13 miles S.W. of Patna.

**RUSTBURN**, in *Farming*, a term provincially used to signify the troublesome weed rest-harrow.

**RUSTENBURG**, in *Geography*, a town of Westphalia, in the territory of Eichsfeld, with a castle; nine miles W. of Heiligenstadt.

**RUSTGADEN**, a town of Sweden, in Dalecarlia; 23 miles S.S.W. of Fahlun.

**RUSTI**, or **RUSR**, in *Biography*, born in 1744, was maestro di cappella, at Barcelona, in 1767. He studied in the conservatorio of La Pietà at Naples, and afterwards under Rinaldo di Capua. His first opera, "La Contadina in Ceste," was composed for Venice in 1764. He went from Venice to Barcelona, where he composed "l'Idolo Cinese," in 1774, "Amor Bizzazzo" in 1775, and "Alessandro nell' Indie," the same year. "Il Baron di terra asciutta," 1776; "Il Socrate Immaginario," 1776; "Il Giove Immaginario;" "Il due protetti," 1777. His operas were much esteemed in Italy.

**RUSTIC GODS**, *Dii Rustici*, in *Antiquity*, were the gods of the country, or those who presided over agriculture, &c. Varro invokes the twelve *dii consentes*, as the principal among the rustic gods; *viz.* Jupiter, Tellus, the Sun, Moon, Ceres, Bacchus, Rubigus, Flora, Minerva, Venus, Lympha, and Good Luck. Besides these twelve arch-rustic gods, there was an infinity of lesser ones; as Pales, Vertumnus, Tutelina, Fulgor, Sterculius, Mellona, Jugatinus, Collinus, Vallonia, Terminus, Sylvanus, and Priapus. Struvius adds the Satyrs, Fauns, Sileni, Nymphs, and even Tritons; and gives the empire over all the rustic gods to the god Pan.

**RUSTIC**, in *Architecture*, expresses a manner of building in imitation of simple or coarse nature, rather than according to the rules of art.

**RUSTIC Fasti**. See **FASTI**.

**RUSTIC Fountain**. See **FOUNTAIN**.

**RUSTIC Freeze**. See **FREEZE**.

**RUSTIC QUOINS**, by Vitruvius called *lapides minantes*. See **RUSTIC QUOIN**.

**RUSTIC Services**. See **SERVICE**.

**RUSTIC Work** is where the stones in the face, &c. of a building, instead of being smooth, are hatched or picked with the point of an instrument.

**RUSTICS, Regular**, are those in which the stones are chamfered off at the edges, and form angular or square recesses

cesses of about an inch deep at their jointings, or beds, and ends.

RUSTIC *Order*, is an order decorated with rustic quoins, rustic work, &c.

Felibien says, it is properly where the several parts of the five orders are not exactly observed; but this confounds rustic with Gothic.

RUSTICI, FRANCESCO, in *Biography*, a native of Sienna, born about 1595, was a disciple of Francesco Vanni. His taste led him afterwards to adopt the style and subjects of Caravaggio. A dying Magdalen in the gallery at Florence, and a Sebastian in the Borgheze palace at Rome, are in that manner, though with more selection of form. He studied at Rome the works of a Caracci and Guido, not, however, to the loss of his own peculiar style. His most renowned work is the Annunciation, at Sienna. He died in the prime of life, in 1625.

RUSTICIANA, in *Ancient Geography*, a town of Hispania, in Lusitania, on the left bank of the Tagus, to the E. of Norba-Cæsarea, and W. of Augusto-Briga.

RUSTICOLA, in *Ornithology*, a species of *Scolopax*; which see.—Also, a species of *tringa*. See *TRINGA Calidris*.

RUSTICULA, a name by which Aldrovand, and some other authors, have called the godwit, more commonly known by the name *agocephalus*. See *SCOLOPAX Egocephala*.

RUSTICULA *Brazilensis*, the name given by Mr. Ray, and some others, to the guarauna, a water-bird of the Brasils, of the size of our snipe. See *SCOLOPAX Guarauna*.

RUSTONIUM, in *Ancient Geography*, a town of Africa, on the coast of Mauritania Cæsariensis, between the river Savus and the town of Ruficibar, according to Ptolemy. It is called Rufconia Colonia by Pliny; Rungoniæ Colonia by Antonine; and according to Livy, the Africans called it Rufconina.

RUSTRE, in *Heraldry*, a bearing of a diamond shape, pierced through in the middle with a round hole.

RUSUBESER, TACKSIBT, in *Ancient Geography*, a town of Africa, upon the coast of Mauritania Cæsariensis, according to Ptolemy, situated to the E. of Rufucurium, between Ionnyum and Rufazus.

RUT, in *Hunting*, &c. a term used for the venery or copulation of deer.

For the terms which obtain in respect of this and other beasts of game, with the noise they make during the acts, see *HUNTING*.

The rutting-time with the hart begins about the middle of September; and holds two months: the older they are the better, and the more beloved they are by the hinds, and the earlier do they go to rut. At this time they will turn head, and furiously make at any living creature. It is easy killing them at this time; their whole business being to scent and pursue the track of the females; scarcely feeding at all. The young herd are forced to fly with great precipitancy, when the hart comes in sight of his mate. If there be any other of bulk, they will dispute it very hotly with their horns. As the season expires, they withdraw, and dig themselves holes in which to lie to assuage the strong fervour of their lust: when become a little sweet, they return to their pasture, and live in herds.

The rutting or touring time of the roe-buck begins in October, and lasts only twelve or fifteen days. When this is past, he casts his horns.

After the hind is filled, she keeps no more company with the male till she be delivered. But the doe always accompanies her paramour till her time approaches, when she re-

tires, for the safety of her young, which he would otherwise kill.

RUT, in *Rural Economy*, a track or narrow opening formed in a road by the wheel of a cart or other carriage, which has but little breadth. Ruts of this sort are often dangerous and troublesome, when they become of any considerable depth; therefore they frequently stand in need of being filled in and rendered even with the other surface. In order to do this with the best effect, the insides of them require to be well loosened with the point of a pick, that a firm bed may be given to the fresh stones which are put in, and at the same time, the protuberances about them, if there should happen to be any, may be chipped off and removed. And still further to prevent the fresh stones from being displaced, it is necessary that they should be covered in with part of the loosened or other materials, and the whole firmly rammed down, or otherwise driven in, so as to give the part, thus put in order, not only the evenness of surface, but, as much as possible, the firmness of the rest of the road. This sort of accuracy may be readily attained by a little practice and experience.

All the minor ruts, depressions, and dimples or hollows in roads which are of any consequence, should always be made up and secured in the same manner, as no water should ever be suffered to stand on any part of the surface of them.

An implement of the three-pointed pick kind is often found extremely useful and convenient in trimming and filling in ruts in this way, as well as for rendering the surface even and regular. See *PICK*.

RUT of the Sea, is where it dashes against any thing.

RUTA, in *Botany*, an ancient Latin name,  $\rho\upsilon\tau\alpha$  of the Greeks, which lexicographers derive from  $\rho\upsilon\omega$ , to flow, in allusion to some reputed expelling qualities of the plant. The word is rather perhaps, as De Theis observes, not capable of explanation, being nearly the same in all the most ancient European languages; *ruz* in Runic; *rude*, *ruta*, or *rutu*, in Anglo-Saxon; *rutiza* in Sclavonian. Hence it is *rut* in English and French; *ruta* in Italian; *ruda* in Spanish and Portuguese; *rute* in German; *rhy'w* in Welsh.  $\rho\upsilon\tau\alpha\sigma$ , a Greek synonym of  $\rho\upsilon\tau\alpha$ , is derived from  $\rho\alpha\upsilon\tau\alpha$ , to congeal or repress; and supposed to refer to a quality in the plant, opposite, in some respects, to the above-mentioned. This latter name is used by Linnæus for a genus nearly akin to *Ruta*; see *PEGANUM*. If etymology were a sure guide to the virtues of plants, rue might be taken by monks, who wish to keep their vows, and by nuns, who have broken theirs. But we believe its efficacy, in either case, as uncertain, as the object is unworthy of consideration.—Linn. Gen. 210. Schreb. 286. Willd. Sp. Pl. v. 2. 542. Mart. Mill. Dict. v. 4. Ait. Hort. Kew. v. 3. 34. Sm. Prodr. Fl. Græc. Sibth. v. 1. 271. Juss. 297. Tournef. t. 133. Lamarck Illustr. t. 345. Gærtner. t. 111.—Class and order, *Decandria Monogynia*. Nat. Ord. *Multifloræ*, Linn. *Rutaceæ*, Juss.

Gen. Ch. *Cal.* Perianth inferior, in five deep segments, short and permanent. *Cor.* Petals five, spreading, nearly ovate, concave, with narrow claws. *Stam.* Filaments ten, awl-shaped, spreading variously, the length of the corolla, broadish at the base; anthers incumbent, simple, very short. *Pist.* Germen gibbous, cut crosswise, surrounded with ten melliferous pores at the base, and raised on a *receptacle* pierced with as many similar pores; style central, erect, awl-shaped; stigma simple. *Peric.* Capsule gibbous, five-lobed half way down, of five cells, bursting elastically at the summit of each lobe. *Seeds* numerous, rough, angular, somewhat kidney-shaped.

Obs.

Obs. *R. graveolens*, and some others, in all except the primary flowers, exclude one-fifth of every part of the fructification. In *R. chalepensis* the petals are fringed at the base.

Ess. Ch. Calyx in five deep segments. Petals concave, Receptacle furrowed with ten honey-bearing pores. Capsule lobed. Seeds numerous. Anthers simple.

1. *R. graveolens*. Common Rue. Linn. Sp. Pl. 548. Willd. n. 1. Ait. n. 1. Bulliard Herb. t. 85. (Ruta; Matth. Valgr. v. 2. 95. *R. hortensis*, et *montana*; Ger. Em. 1255.)—Leaves repeatedly compound; leaflets oblong; the terminal one obovate. Petals entire.—Native of the south of Europe. Frequent in the islands of the Archipelago. A hardy shrub, cultivated, time out of mind, in our gardens, where it flowers from June to September, and propagates itself spontaneously by seed. The stem is bushy, rising to the height of several feet, round, smooth, branched. Leaves alternate, stalked, twice or thrice compound, smooth, of a deep blueish glaucous hue; their leaflets oblong or obovate, entire, tapering at the base. Stipules none. Flowers of a rather dull yellow, copious, in terminal corymbose panicles; the terminal ones only having the full number of each of the parts of fructification, while the rest are octandrous and four-cleft. Petals jagged at the extremity; angular, but not fringed, at the base. The stamens of this, and perhaps all the other species, are remarkable for their progressive approach to the stigma, over which they in turn drop their pollen and retire. Every part of the plant when rubbed, or touched, has a peculiar acrid pungent smell, too strong to be agreeable. The bruised leaves excoriate the lips and nostrils, if incautiously applied, as they often are, to counteract bad smells; rue being supposed powerfully to prevent contagion. Its internal use is unsafe; yet we have known it eaten with bread and butter in no small quantity; not altogether with impunity. Botanists distinguish two varieties; the wild, which has more oblong leaflets, or segments, and the garden rue, which has rounder ones. Gerarde has transposed the cuts of these, borrowed from Dodonæus.

2. *R. montana*. Mountain Rue. Ait. n. 2. Willd. n. 2. (*R. legitima*; Jacq. Ic. Rar. t. 76. *R. fylvestris*; Camer. Epit. 495. *R. fylvestris minima*; Ger. Em. 1255.)—Leaves repeatedly compound; leaflets all linear. Branches of the panicle racemose. Petals entire.—Native of dry hilly situations in the south of Europe. Dr. Sibthorp found this species in various parts of Greece, and the neighbouring countries, and justly considered it as the *πρωταρσινος*, or Mountain Rue of Dioscorides, for which most of the commentators of that old writer have mistaken the wild, or narrower-leaved, *R. graveolens*. This is a hardy perennial herb, rather than a shrub, flowering in autumn in our gardens, where, however, though cultivated by Gerarde, it is now rarely to be seen. The plant is known by its more humble stature, and especially by the very narrow leaflets. The radical leaves are crowded into a dense tuft. Most of the flowers are four-cleft, as in the former. The branches of the panicle are racemose, and elongated. Capsule not half so big as in the Common Rue.

3. *R. chalepensis*. African Rue. Linn. Mant. 69. Willd. n. 3. Ait. n. 3. Sm. Fl. Græc. Sibth. t. 368. (*R. tenuifolia*, *florum petalis villis scætantibus*; Morif. scct. 5. t. 35.)—Leaves repeatedly compound; leaflets oblong or obovate. Petals with fringe-like teeth.—Native of Africa, as well as of Zante, and the isles of the Archipelago. A common greenhouse shrub, flowering at various seasons, and chiefly distinguished from the Common Rue by its larger flowers, whose petals are copiously fringed with taper teeth. Many

of the flowers are four-cleft, and the foliage varies in breadth, as in that species.

4. *R. pinnata*. Wing-leaved Rue. Linn. Suppl. 232. Willd. n. 4. Ait. n. 4.—Leaves simply pinnate; leaflets lanceolate, tapering at the base, bluntly serrated. Petals somewhat notched.—Native of rocks in the Canary islands, from whence it was brought by Mr. Mallon to Kew, in 1780. This is a greenhouse shrub, flowering in spring and summer. It is very distinct from all the foregoing, resembling the first in size and inflorescence, but the flowers are smaller, with crenate, or slightly toothed, petals. The leaves are very different, composed of two or three pair of opposite leaflets, above an inch long, various in breadth, more or less obtuse, with unequal blunt serratures; the odd one rather the largest, on a long stalk.

5. *R. patavina*. Three-leaved Rue. Linn. Sp. Pl. 549. Willd. n. 5. Sm. Fl. Græc. Sibth. t. 369, unpublished. (*Pseudo-ruta patavina trifolia*, *floribus luteis umbellatis*; Mich. Gen. 22. t. 19.)—Leaves ternate, sessile. Stamens hairy. Germen crested.—Originally discovered by Micheli on a hill near Arqua, not far from Padua. Dr. Sibthorp met with it on mount Parnassus. Linnæus had no specimen, nor is the plant known in our gardens, so that it seems not to have fallen in the way of many botanists. The root is woody and perennial. Stems several, a foot high, erect, round, downy, leafy, branched at the base only. Leaves numerous, downy, of a light, rather glaucous green, alternate, sessile, each composed of three, nearly equal, narrow, obtuse, entire, slightly revolute leaflets, about an inch long. Flowers five-cleft, in a terminal, dense, cymose panicle. Calyx hairy, spreading. Petals ovate, obtuse, entire, of a pale dull yellow, with a green central rib. Stamens ten, not so long as the petals; their filaments hairy half way up. Germen five-lobed, covered with glandular tubercles, and crowned with numerous oblong, notched, crest-like, leafy scales.

6. *R. linifolia*. Broad Flax-leaved Rue. Linn. Sp. Pl. 549. Willd. n. 6. Ait. n. 5. Andr. Repos. t. 565. Sm. Fl. Græc. Sibth. t. 370, unpublished. (*R. fylvestris linifolia hispanica*; Bocc. Mus. v. 1. 82. t. 73. f. 3. Barrel. Ic. t. 1186. *R. montana*, *foliis integris subrotundis*; Buxb. Cent. 2. 30. t. 28. f. 2.)—Leaves simple, obovate. Stamens hairy. Germen without a crest.—Native of Spain, Cyprus, and various parts of Greece. The plant of Buxbaum, gathered by him in fields, after harvest, near Rodostro, in Thrace, as far as can be discerned from his imperfect figure, does not deserve to be considered as even a variety. This agrees with the last in general habit, but is more robust, the flowers more numerous, and of a deeper yellow. Leaves much broader, less glaucous, and all simple and solitary. Stamens much dilated, and very hairy, in their lower part. Germen roundish, five-lobed, ten-furrowed, rough with small granulations, but entirely destitute of the leafy crell, which, though so remarkable in *R. patavina*, is not expressed by the generally exact Micheli. The name of *linifolia*, usually alluding to the Common Flax, is not well adapted to the plant we have been describing, except we understand it as referring to some of the broad-leaved yellow species of *Linum*, between which and this *Ruta* there exist indeed many points of resemblance.

7. *R. fruticulosa*. Narrow Flax-leaved Rue. Labillard. Syr. fasc. 1. 13. t. 4. Willd. n. 7. (*R. orientalis*, *linariæ folio*, *floræ parvo*; Tourn. Cor. 19. Buxb. Cent. 2. 30. t. 28. f. 1.)—Leaves simple, ovato-lanceolate. Clusters corymbose, of few flowers. Stamens hairy at the base. Germen hairy, without a crell.—Gathered in Syria, near Damascus, by our worthy friend M. Labillardiere, to whom

whom we are obliged for a specimen. This species is not known in gardens. The *stem* is shrubby, a span high, much branched, particularly from the base, round, downy, leafy. *Leaves* scattered, sessile, downy, about half an inch, or rather more, in length. *Flowers* small, five-cleft, yellowish, four or five together, forming short simple *clusters* at the summit of each *branch*. *Calyx* fringed with hairs, like the lower part of the *stamens*. *Germs* deeply five-lobed, clothed with fine hairs. The *petals* have short claws, more evident, as Willdenow observes, than in the preceding.

RUTA, in *Gardening*, contains plants of the under-shrubby evergreen kinds, of which the species cultivated are: the common rue (*R. graveolens*); the mountain rue (*R. montana*); the African rue (*R. chalepensis*); and the three-leaved rue (*R. patavina*).

In the first sort the varieties are; the common broad-leaved rue, the narrow-leaved rue, and the variegated-leaved rue.

And in the third kind there are varieties with broad leaves and with narrow leaves.

*Method of Culture*.—All the species and varieties of these plants may be readily increased by seeds, slips, and cuttings. The seed should be sown in the open ground in March or April, on a bed of light earth, raking it in: the plants soon come up, which, when two or three inches high, should be planted out in nursery-rows, and watered till fresh rooted. And from the scattered or self-sown seeds of the common sort, many young plants often rise in autumn and spring, which form good plants; but by slips or cuttings is the most expeditious method of raising all the sorts, as every slip or cutting of the young wood will readily grow. It is the only method by which the different varieties can be continued distinct. The slips or cuttings should be made from the young shoots six or eight inches long, and planted in a shady border, in rows half a foot asunder, giving a good watering, and repeating it occasionally; by which they will soon emit roots below and shoots at top, so as to form little bushy plants by the autumn following. And they all afford variety in the borders and other parts of gardens and pleasure-grounds, and the first sort and varieties are also useful medicinal plants. The third sort should have a dry soil and sheltered situation, otherwise it does not succeed well.

Some of these plants may be used for variety in the borders and other parts of pleasure-grounds, gardens, &c.

RUTA, in the *Materia Medica*. See RUE.

RUTA BAGA, in *Agriculture*, a plant of the turnip kind, which has lately been introduced into field culture with great benefit to the farmer, as affording a supply of green food for the support and fattening of sheep or other live-stock, between the common turnip and grass seasons. This root has been considered by some as a mere variety of the yellow turnip, but it is found to differ very materially from it both in texture and other properties. With respect to the top, or stem, it has something of the appearance of the rape, or cabbage kind; and the bottom, or that part of the root-bulb which is above the surface of the ground, is covered by a thick, green, tough cuticle or skin, which in some is smooth, but in others quite rough, and the internal fleshy part is of a dense, close, firm consistence, having a yellowish tinge, nearly similar to that of the horn carrot. It has indeed been suspected by some that there are two varieties of this valuable plant, the one having a *white*, and the other a *yellow* root, the latter being considered as much the best; but this seems to have arisen from their having been grown from seed collected in the neighbourhood of plants of the turnip or

cole kinds, as is fully shewn in the Surveys of the North Riding of Yorkshire and Nottinghamshire.

But the great inducements for the farmer to enter freely into the culture of this root are, according to Mr. Young, 1. If he has the right sort of feed, the root yellow in flesh, and rough in coat, it lasts through all frosts, and may be depended on for sheep quite through the month of April, though drawn two months before, and spread on a grass field. 2. It is an excellent and nourishing food for sheep, and also for any sort of cattle. 3. It is equal to potatoes, in keeping stock swine: a point of very great consequence. 4. It is, next to carrots, the very best food that can be given to horses. 5. It is sown at a season which leaves ample time, in case of a failure, to put in common turnips, or cabbages.

And in regard to the soils most proper for this root, those of the good, rich, loamy kinds are perhaps the best; but it may be grown to advantage on many of those that are too moist and heavy for the common turnip; where the land has been brought into a tolerably perfect state of pulverization and mellowness, and been well enriched with manure before the seed was put into the ground, or the plants set out upon it; as it has been perhaps from the want of this full preparation of the land, and the putting in the seed of a bad kind, and at too late a period, that cultivators of this useful root have been so frequently disappointed in obtaining good crops.

*Seed*.—In procuring the seed, it should always be collected from such plants as have been transplanted, and which are the most perfect of their kind, as where this is not the case, the cultivator can never be certain of having his plants of the proper sort. The writer of the East Lothian Report on Agriculture has indeed observed, that as no dependence can be placed on the seed purchased in the shops, every farmer ought to raise seed for himself: this may be done with very little trouble, and at no expence; it is only necessary that the seed-plants be carefully placed by themselves, and not allowed to be near other plants bearing flowers or seed, while they are in the same state. The danger seems to result from plants of kinds nearly related to each other mixing the farina of their flowers, when growing to seed. The ruta baga seems much liable to some adulteration of this kind, and unless farmers guard against it, by taking the trouble to preserve their own seed, they need hardly expect it genuine.

With respect to the quantity or proportion of seed that is made use of where the broad-cast method is employed, it is generally about two pounds to the acre; but where the drill plan is pursued, a somewhat smaller proportion may be sufficient: however, as it is mostly found difficult to produce a sufficient plant of this crop, it may be advisable never to be too sparing in the article of seed. In all cases new seed is to be constantly preferred, and when the season is hot and dry, it may be of utility to have it prepared by steeping a short time before sowing it.

In what regards the time of sowing, as this plant is much slower in its vegetation than that of the common turnip, it ought to be sown or put into the ground at an earlier period, by which circumstance, it will not only be more forwarded for the hoe, and more fully fixed and established in the soil, but better protected from the attacks of the fly, and the heats of the ensuing summer months. It has been the too common practice of farmers to sow this crop at the same time with that of the common turnip, by which the crops have often failed. But if put in a month or six weeks sooner, it will be found more advantageous, as from about the latter end of April to the middle of May, or perhaps a little later in the northern districts, as is shewn by the agricultural surveys of these counties. In different places dif-

ferent

## RUTA BAGA.

ferent methods are practised in raising these kinds of crops; sometimes, instead of sowing the seed over the land in either the broadcast or drill manner, it is sown upon nursery beds of good rich earth, and after the plants are sufficiently advanced, as where they are about the size of small cabbage-plants, they are transplanted into the field, and set out on raised drills, at the distance of eight or nine inches or more from each other, and a foot or more in the rows. The business of transplanting should, if possible, be performed when the weather is in a moist state. And this may perhaps be the best mode of executing the work where such crops are cultivated only to a small extent; but where they are grown upon a more extensive scale, the former are probably to be preferred, as being more expeditious and convenient, as well as more certain of affording a sufficient plant for a full crop. From the danger of these crops being destroyed by the ravages of the fly, it has been suggested by Mr. Young, that the best culture of this plant is to sow it where it is to remain, broadcast, from the 10th of May to the end of the month; and of all others, the best preparation to secure a crop is that of paring and burning, for the fly being the grand enemy, from its coming so very slowly to the hoe, this operation not only proves by far the best preservative against that enemy, but also pushes the plants on in an accelerated vegetation, and thereby doubly secures the crop. If the seed cannot be thus put in on land so prepared, the next best management is, to sow it after common turnips sown on the land by sheep. If neither method suits, it must be put in on well pulverized soil, very amply manured.

On a well cultivated farm near Hampstead, in the county of Middlesex, the method of culture and expences attending it were these.

### Expences of Cultivation of an Acre of Land.

	£	s.	d.
Three ploughings, at 10s. - - -	1	10	0
Three harrowings, at 5s. - - -	0	15	0
Cleaning by hand-picking - - -	0	10	0
Making up drills - - -	0	5	0
Dung and labour of putting it in, half only } allowed to this crop - - -	2	10	0
Covering it up in drills - - -	0	5	0
Seed 2lb. - - -	0	7	6
Drilling in ditto - - -	0	1	0
Horse-hoeing twice - - -	0	1	8
Hand-hoeing twice - - -	0	12	0
Moulding up rows - - -	0	1	0
	6	18	2

And in this mode the crop was very good, being capable of being fold in 1806 at 12l. per acre; the turnips averaging about five pounds weight each, and a large portion rising as high as twelve. The crop was put in upon land that had previously borne winter tares. And under this management the cultivator has no doubt of raising still larger crops.

*After-culture.*—It is evident, that in the after-culture of this plant, from its advancing more slowly to the hoe, that it must require greater attention to keep it clean and free from weeds than that of the common turnip. The business of hoeing, both in the horse and hand methods, must therefore be more diligently practised, repeating the operations as often as may be sufficient for the purpose, keeping the mould constantly well broken down, and applied to the roots of the plants.

And the plants of the Swedish turnip are liable to be af-

fectured by the same causes as those of the common turnip, the fly especially, being equally, if not more prejudicial to these crops than those of the common turnip kind. And besides, they are apt to be greatly injured or destroyed by rabbits, hares, and different sorts of birds, both in their tops and roots.

It may be noticed, that there is much difference in the statements in regard to the amount of the produce in this sort of crop; but when it is put in at a sufficient early period, and the ground prepared and managed in the manner that has been stated above, it will probably in general equal, if not surpass, that of the common turnip. And when it is considered that the flesh of the roots is much more solid and compact, and abounds more with nutritious matter, the *real* quantity of food which they afford must probably be much greater. In the trials of the above cultivator, they are found to go one-third further in the fattening of cattle or other animals, than the common turnip. And the Rev. Mr. Clofe, in the ninth volume of the Bath papers, has recorded an experiment in the transplanted method upon ridges of the same dimensions as those used for the common turnip, and the produce was found, after they had sustained the frosts, in the month of March, without either tops or tails, and when perfectly free from dirt, to be thirty-two tons on the acre. Mr. Daiken has stated in the Nottinghamshire Report, their advantage in the feeding of horses for a few acres to have been as high as thirty pounds the acre. And in the experiments of others, as detailed in the Agricultural Report of the North Riding of Yorkshire, they have likewise been found in common heavier than those of common turnips, though in appearance, from the closeness of their texture, they did not seem to equal them. This is, however, only conjecture, and is quite at variance with what has been the result in other cases, where actual weighing and measuring have been had recourse to. In common soils, and the ordinary modes of cultivation and application of these crops, the quantity of produce on the acre must probably be rated considerably lower, as well as their value as food for live-stock.

On actually weighing a square perch of each of these different sorts of turnip crops in the month of November, in 1808, which were grown together in the same field, on the very same kind of land, at Quarmer Park, near Lancaster, under the excellent management of Charles Gibson, esq. the respective weights were found to stand thus:

	Cwt.	qrs.	lbs.
Common turnip - - - -	4	2	10
Ruta бага, or Swedish turnip - - -	4	2	7
Difference	0	0	3

Which is a very trifling superiority in favour of the former; and on account of the earliness of the season for the growth of the latter, they would in all probability soon exceed it, as they are well known to increase in size and weight to a considerable later period.

It may be stated, that this sort of crop has been found of vast use in the support of sheep and other sorts of live-stock, in the more late winter and early vernal months, where the common turnip is liable to become rotten; or run up to seed: as being much more easily preserved in a sound condition, from its greater power of resisting the effects of the season, even when taken up, as well as while in the ground. In some situations, in very severe seasons, it is however sometimes a little injured, when left in the ground through the winter. Mr. Clofe has however found, that by having the tops and tails removed when they first begin to shoot, and  
being

## RUTA BAGA.

being stacked, they may be kept till the latter end of May, and later probably if necessary; but which can rarely be the case. In this manner a useful supply of cattle food is provided for that difficult and harassing period, when turnips or other similar sorts of food get scarce, exhausted, or unfit for being employed, and when the grass is not in a state to be made use of by the stock. On these accounts it is of course of admirable advantage for the farmer to be well provided with crops of this kind, to the full extent of his livestock, in bringing them through the difficult months of March, April, and the early part of May. Its application has been to almost all sorts of domestic animals: with neat cattle, both in fattening, and as an ordinary article of food, it has long been in use, it is said, with much greater effect than the common turnip. It is given after being cut or chopped into small pieces: when given to milch cows, it is found to increase the milk considerably, and render it more rich, as well as to give it a finer colour; but we are afraid it in some measure affects the flavour, though some have denied its having this effect.

And sheep succeed well upon it, gaining much more while upon it than on the common turnip, but it has been objected to in this application, from its hardness being supposed to injure their teeth, when the root is well grown: this is, we believe, from experience to be only imaginary.

Also, in the North Riding of Yorkshire, in the store-feeding of hogs, it has been found equal to potatoes. And as a food for labouring horses, it is said to be highly beneficial, as rendering a smaller proportion of oats requisite, not being of so loosening a quality as most other roots. In this application, the roots, after being washed and having their tails cut off, are put as below, and cut or chopped into large pieces by some sort of sharp tool acting in a high sort of tub or box for the purpose. In some of the northern districts it is given both in its raw state, or boiled and mixed with barley dust or broken corn. But as the roots are liable to be greatly injured by exposure after being cut, for this use as well as that of fattening cattle, not more than are necessary for the daily consumption should be prepared at a time.

It may be necessary as well as advantageous after this account of the culture and uses of these turnips, to state the facts respecting them, as they are found in those districts where they are become an article of almost general growth. In Hertfordshire, according to the Agricultural Survey of that district, they have so rapidly made their way, as to be found in the usual management of great numbers of the common farmers: no trivial proof, the writer says, of their observation, knowledge, and good sense. He adds that Mr. Byde has this year (1804) 25 acres of them; a very regular plant, promising a great produce. He finds that sheep will not touch the common turnip, if they can get at these; but they are apt to break their teeth, from the greater hardness and solidity of the root. He also finds that they do not taint the milk of cows, like the common turnip; and are an useful food for horses. He sows them from the 13th of May to the 20th of June. When sown very early, as in May, they are so difficult to keep clean, that he prefers June. Mr. Byde reaps better crops of barley after them than after common turnips. And Mr. Greg, at Westmill, has 25 acres: he has cultivated this crop for some years, and generally on a large scale. He manures for them with yard-muck, or pulverized rape-cake, from six to twenty bushels an acre, according to the soil, usually with about twelve, and sows the seed early in May. He states them, from his experience, to be much better than the common turnips; as they never rot, let the weather be as severe as it

may, nor are they stringy, when consumed late in the spring. He informs him that the barley after them is not so good as after other turnips eat earlier, but much better than when those turnips are consumed as late as the Swedish; that they do not cost more in cultivation, yet are of double the value. The farmers sow them very generally, so that few are to be found who sow none. Mr. Wittington, at Broadwater, is a considerable cultivator of this plant. He prefers them to common turnips, and would substitute them for the greatest part of that crop. He sows soon after the first week in May: for the value in feeding, time of consumption, duration, &c. he knows nothing equally valuable. The Rev. Mr. Keate, at Hatfield, is also considerably in this cultivation, and with much success: he has had crops of them for five years. His crop this year amounts to five acres, which he viewed with great pleasure—a fine regular plant, very luxuriant; equally set out, and quite clean. They were well manured with yard-dung, and the land ploughed four times. He sows in the middle of June: they had been hoed at the expence of seven shillings *per* acre: part of the field had yielded a crop of winter tares. They have usually come to a large size on Mr. Keate's farm. He has fed horses with them, entirely to his satisfaction; and cuts the roots with a very simple, effective turnip-slicer: each horse had a bushel every day, with chaff, but no oats; they did their work very well, and became fat while they were eating this turnip. Cows also do well on it; nor does it give their milk or butter any taste, but increases their milk considerably. They are excellent also for fattening sheep. The culture is become very general through this county: so that there are few farmers in it who are without a field of this excellent plant. He likewise says that the marchioness of Salisbury has many acres in great perfection, and finds them of incomparable use. But Mr. Stephenson remarks, that their most important use is so late in the spring, that it is difficult to introduce them in a regular course, and sow spring corn in time: he thinks them rather applicable to a few fields out of a regular rotation for sowing some other crop than barley or oats after them; such, for instance, as winter tares. He may add buck-wheat also. Cows do very well on Swedish turnips without hay, and give much milk; and these roots last longer for sheep in consumption than an equal quantity of common turnips, but the sheep do not thrive equally. Mr. Deerman, of Altwich, is a great friend to them; but observes, that they throw the land out of course: as they are most useful so late in the season, that spring corn cannot be sown after them, he thinks the best way is to sow common turnips for the next crop, by which means also the land would be brought into remarkably high order. Mr. Marsh, his neighbour, makes the same observation, but has, however, always sown spring corn after them.

On this subject it is further stated, that Mr. Clarke, of Sandridgebury, has cultivated them eight or nine years with great success; having generally from 20 to 25 acres annually. He sows the last week in May, and finds no difficulty with the succeeding crop, which is always barley, and as good as any, and often the best on his farm. He has eat them so late as the 6th of May. Mr. Cotton, at Hempstead, cultivates, and has the highest opinion of them; and has only one objection to them, their slow growth, which retards their hoeing. His corn grown after them is good. Mr. Pickford, at Market-street, has 30 acres this year, a beautiful regular crop. He has from experience a great opinion of them, when applied to the fattening of oxen and sheep, and to the feeding of hogs; in which last application he thinks them

them superior to potatoes. He saw above 500 hogs on his farm. On finding these roots so profitable, he grew no more potatoes. But Mr. Chapman, of Hitchin, is of opinion that this root demands a richer and stronger soil than the chalks and loams about Hitchin; for they have been cultivated some years, dunged for, and twice hoed, but the success has not been great. The farmers entertain a high opinion of them. And Mr. Hale, of King's Walden, has cultivated them four years; he sows them the latter end of May broad-cast; hoes them twice always, picks charlock by hand, and uses all for sheep and lambs: they have been very valuable indeed. In the spring of 1800, he could have sold the crop, eight acres, at 10*l.* per acre. In the beginning of March, common turnips being over, 200 sheep and 200 lambs, and 140 other sheep, were kept on them near seven weeks. The same field was to have been sown with barley, and ploughed twice, but being late, was sown with Swedish turnips again, and the crop, without manure, except two cart-loads of pigeons' dung, was in every respect as good as the other. This year the land was ploughed once, and sown with white oats, and the crop was equal to full eight quarters per acre. Last year he had fifteen acres, and this year eleven, of this root. Mr. Roberts, the steward, who has a farm himself, has nine acres this year, and intends never to be without them; being perfectly convinced that they are a most useful crop. The writer has not seen many finer crops than Mr. Hale's, and all the parts of a full yellow colour. Lord Clarendon has five or six acres every year, and finds them of capital use. His lordship sows in May, on land, upon which, in autumn, the dung was ploughed in, as he thinks it very essential for this crop; he sirs the land in April, and ploughs it in May for sowing: he sows three pounds per acre: they are hand-hoed twice: he first uses them in the beginning of March: he did not eat them last year until the 24th of April, and had a large barley crop after them. They run very much to top, more than common turnips, and if his lordship had none, he would buy them for the spring at a much greater price than common. He feeds first with ewes and lambs, and then store sheep follow and eat clean. Good barley always grows after them. He has only gravels to sow them on. Mr. Parker, at Munden, has also cultivated them four years: he has twenty acres this year, and had sixteen last year; and as many the year before. The yellow-fleshed turnip is much the best. He sows in May, hand-hoes twice, and has always very good crops. He feeds them on the land with sheep; and draws them for horses, for which stock they are very useful: he uses them also for beasts of all sorts; they are of prodigious utility in point of duration, and excellent, late in the spring, for straw-fed beasts. He grows as good spring corn after them as after common turnips; but manures for them rather higher than for other sorts. They are best on loamy land; do well on good gravel; but, on very sharp gravel, they should not be sown. His twenty-acred field this year, for such an extent, is the finest crop that the writer ever saw, the earl of Winchelsea's at Burley alone excepted; yet this crop is from the second sowing in June. Mr. Calvert, at Albury, has had them four years; has now seven or eight acres: he sows them at the end of May; and finds that there is not any thing so good for every animal for which he has tried them. He once gave a few to some fattening wethers that were at common turnips, and after eating them, they would not take again to the common turnips without much starving. He has had Swedish turnips and common turnips on each side of them in the same field, and sheep turned into the field would not touch the common turnip, but seized on the Swedish immediately. The yellow-

fleshed is much superior to the white; and the rough-coated to the smooth skins. His present plan is, to assign two fields, well situated for the cattle and sheep, and to have one every year under the Swedish, and the other in common turnips, to follow each other, by which means no inconvenience will result from not getting the Swedish off in time for barley. But Mr. Hill, of Whittle, thinks they injure the land by late keeping and running to feed. However, Mr. Foster, of Royton, has a high opinion of them; and observes that they are peculiarly valuable in a chalky district, where turnips *must* be fed very early, or the barley crop lost; Swedish then come in when most wanted.

It is noticed that the writer concludes on these statements, that the plant, where the soil is not sufficiently rich, may probably give way; but as to the more common objection of some, that barley cannot follow, not to speak of the success with which so many others sow that grain, it may be observed, that the right system, where the objection has really some foundation, is hinted at in the preceding notes: common turnips, winter tares, or buck-wheat, may properly succeed; and this double fallow can scarcely fail of answering in the uncommon degree of cleanness, which must be the consequence. Another plan is, to draw such as would remain too late, and strew them on grass for cattle or sheep. The objection is, therefore, in any case easily remedied. And in the Agricultural Survey of Norfolk, it is stated that Mr. Walker, of Harpley, has cultivated them for some years with great success, generally has from twenty to thirty acres annually; feeds them off with sheep and bullocks, and can depend on them when common turnips are all rotten. This crop in 1800, notwithstanding the drought, was very fine. And Mr. Coke, of Holkham, has thirty acres this year, has cultivated them for several years with the greatest success, and esteems them as a very valuable acquisition. Mr. Syble, of South Walsham, had last year a crop of these roots, which came to a good size, but they were so hard that no stock which he tried liked them. But Mr. H. Blythe, of Burnham, had a field of them of great use in the spring; this year he has ten acres.

It may be remarked, upon the whole, that as the objections to this root, on the score of its being difficult to take up, and of its hurtful and inconvenient effects in remaining upon the land to so late a period, seem not well founded, or to be capable of being readily obviated, there can be no doubt but that it must be found of great advantage on most farms where much live-stock is kept, as a food to succeed that of the common turnip late in the spring, when scarcely any other sorts are to be had in plenty for the feeding of live-stock.

In some other districts they are also cultivated to considerable extent, and with much success and advantage, as in those of Oxfordshire, Essex, &c.: their introduction is likewise attempting in many others, where their utility and value are beginning to be known. In the first of the above counties, Mr. Edwards, who cultivates them largely, has a great opinion of them as a resource, when nothing else is to be had, particularly as a spring feed: though they lose their leaves in the winter, what they produce in the spring is very great. As good barley is got after them, in his management, as after common turnips, but they are supposed to draw the ground rather more: it is not known what could be done without them. Mr. James Payne also grows them largely, and has the highest opinion of their utility. They are found by him to be the most profitable of all ways, when applied in the fattening of young pigs called porkers; which should run about as usual during the time of their becoming fat, only having as much of this kind of food as

they can eat. Nine porkers fed in this way paid each sixpence in the day, for six weeks together; which is a remarkable fact, and highly valuable for the cultivators of this root to be acquainted with. Others have had equally great success in the same way of using this root. Mr. Salmon likewise cultivates this root with much success, putting in the crops of it in the latter end of May, or early in the following month: uses his own seed, which produces roots which are single with yellow-coloured flesh, and quite round in form: three hoeings are given in raising them. They are applied as food for calves, sheep, cows, and pigs, being extremely useful in each of such modes: the pigs, however, have only the hulls, after other cattle. They are made use of to the end of April, when spring wheat is sown on the same land after them, and as good crops are procured as after any other sort of crop. They are supposed to produce so much fertility, by the abundant stock which they keep, that barley, if sown after them, would be all straw.

In fact, the farmers of this district are stated to feel a thorough conviction of the importance which is attached to them, and to be well informed of the best modes of applying them in their consumption. Their use in feeding sheep is well understood, and great reliance is placed on them as a late feed in difficult spring seasons. The improved practice of giving them sliced in troughs to penned sheep, is highly worthy of the farmer's attention; and their application in the fattening of oxen, from stores laid up and preserved for that purpose, is of great importance, and highly deserves to be imitated by different other districts. And the discovery which has been made of the young pigs termed porkers being most profitably fattened upon them, is alone of very great consideration: but it requires to be further and more fully ascertained, by a set of experiments instituted expressly for the purpose; as, should the same fact turn out to be well established, not only in this case, but upon soils superior in fertility to the red sand lands in the north of this district, it would be a most valuable discovery indeed to the farming interests of the whole country.

The practical circumstance of sowing winter tares upon a rich and full manuring, eating them off upon the land, and then immediately putting in a crop of this sort, is likewise supposed a method of cultivation which can scarcely be exceeded, on such soils as are of a good quality. The fact of the barley crops after this root being found full as good as those after common turnips, also deserves to be attended to; as the cultivators who maintain it are perfectly aware, that roots, standing in the ground late in the spring, must necessarily tend to draw the land more than if they were consumed at an earlier period; but this circumstance is found to be compensated by the sheep, or other stock, remaining so much longer upon the ground.

In cases where this sort of crop is removed from the field, there is no more objection on that account than in the case of common turnips; but it may be done with the very superior advantage, that this root can be kept in any method with perfect safety, which is well known cannot be done with common turnips.

And in the latter of the above counties, the farmers find them equally valuable and useful in feeding and fattening different sorts of live-stock. By some they are thought to be uncommonly useful, and to feed stock in a manner which shews their quality to be very rich in nourishment. But when kept late, spring tares, it is thought, should be sown after them, as barley is hazardous; and others find them much better for fattening sheep and bullocks than common turnips. They are the grand staple article for the latter purpose, in some instances; one bushel of them being found

worth three of common turnips, in such an application. The beasts and hogs, which have once tasted them, refuse other turnips afterwards. Eight or nine quarters of barley are taken from the acre, in some cases, after this root; but the manuring for it was large. The leaves of the crops have sometimes been fed off in the autumn, which did not in the least hurt them; and though the sheep ate into some of the roots, the frost had no other effect than to cover the wound with a thin skin of putrefaction, leaving the rest of the root perfectly sound. Half the crop has been drawn for horses, which are found to be very fond of them; and they were ascertained to be nearly as useful as carrots in this application. They are also excellent for feeding and rearing young calves. The best crops here seem to be raised by full manuring, especially with long, fresh, unstirred dung from the farm-yard.

This root is likewise beginning to be esteemed, and a favourite with some farmers, in the county of Berks, where it is found to have several advantages over the common turnip, especially those of resisting the severest frosts, and of being as good and fit for use in the beginning of the new year, as the other kind is at the end of the old one, and thus forming a link in the succession of feed for live-stock, and saving the expence of hay and other articles. From its sweetness, superior firmness, and more nutritious juicy quality, it is found more quick in its fattening properties; but from its more slow growth, it is supposed to exhaust the land to a greater degree: yet, where there are rich, deep, loamy soils, it is undoubtedly entitled to a preference, on these and many other accounts.

In Devonshire, in the practice of Mr. Exter, the relative produce between the transplanted root of this kind and the Norfolk green turnip, under precisely the same circumstances as to the nature and condition of the land, is stated by Mr. Vancouver as 628 to 851; giving a most decided preference to the former, after amply defraying the additional expence of transplanting.

RUTA MURARIA, in *Botany*, Wall Rue, a common little European Fern, so called from its general place of growth, and the resemblance of its deep glaucous green fronds, to the leaves of Rue. See RUTA, and ASPLENIUM, species 21.

RUTACEÆ, so named from the genus *Ruta*, which is one of the tribe, is a natural order of plants, the 81st in the system of Jussieu, or the 21st of his 13th class. The characters of this important class are given under GERANIA. Of the order now before us, Jussieu must be considered as the founder. We shall, therefore, exhibit his own view of it, though that view is very incomplete, and capable of being much improved and elucidated by recent discoveries.

*Calyx* of one leaf, often in five deep segments. *Petals* mostly five, alternate with the segments of the calyx. *Stamens* definite, distinct, generally ten, alternately opposite to the petals and to the calyx. *Germen* simple; style solitary; stigma simple, or rarely divided. *Fruit* either of many cells, or many capsules, the cells or capsules mostly five, each containing one or more seeds, inserted into the inner angle. *Corculum* flat, in a fleshy albumen. *Stem* either herbaceous or shrubby, rarely arboreous. *Leaves* in some alternate, naked; in others accompanied by stipulas, in which case they are most usually opposite. *Flowers* either axillary or terminal.

SECT. 1. *Leaves with stipulas, and mostly opposite.*

This section consists of *Tribulus*, *Fagonia*, *Zygophyllum*, and *Guaiacum*, all Linnæan genera.

SECT. 2. *Leaves alternate, without stipulas.*

*Ruta*, *Peganum*, and *Diſſamnus*.

Sect. 3. *Genera akin to the Rutaceæ.*

*Melianthus*, *Dioſma*, *Empleurum* of Solander, and *Aruba* of Aublet.

The author obſerves that the plants of the firſt ſection are moſt akin to his *Gerania*, but differ from that order in having a fleſhy *albumen* and a ſtraight *corculum*. Their habit is more like *Caffia*, and its allies, among the leguminous family, which have likewiſe abruptly pinnated leaves, attended by ſtipulas, as well as ten ſtamens with one ſtyle; but theſe *Rutaceæ* differ in having oppoſite leaves, a fruit of many cells, and eſpecially ſtamens inſerted into the receptacle, beneath the germen. He inquires whether *Quaſſia*, *Thryallis*, *Trigenia*, &c. be akin to them? Alſo whether his two ſections are with propriety combined together, and whether they ought not rather to conſtitute different orders, diſtinguiſhed by the fruit? However this may be, he adds, the *Rutaceæ* are diſtinguiſhed, by the definite number of their ſtamens, from both *Tiliaceæ* and *Ciſti*, while the alternate ſituation of thoſe organs with reſpect to the corolla, diſtinguiſhes this order from the *Berberides*.

The true idea of the order before us muſt be taken from Juſſieu's ſecond ſection, compoſed of *Ruta*, *Peganum*, and *Diſſamnus*, to which are, moſt indubitably, to be added from his third, *Dioſma* and *Empleurum*; but ſcarcely the *Aruba* of Aublet, and certainly not *Melianthus*. The diſcoveries in the ſouthern hemisphere have made botaniſts acquainted with many new genera of this tribe. (See *PHEBALIUM*, *CORRÆA*, *CROWEA*, *ERIOSTEMON*, and *MELICOPE*.) *Tetratheca*, however, is erroneouſly mentioned, under the laſt article, as belonging to the ſame family. We have always been inclined to refer *OXALIS* to it, (ſee that article,) rather than to the *Gerania*, on account of the elaſtic *arillus* of its ſeeds, ſo analogous to what occurs in many *Rutaceæ*; at leaſt *Oxalis* is a connecting link between the two orders.

The *Rutaceæ* are nearly all ſhrubby; their *leaves* without *ſtipulas*, coriaceous, or ſlightly fleſhy, moſtly ſmooth, moſtly of reſinous dots ſtrongly ſcented, ſometimes acid; uſually alternate and ſimple; in ſome inſtances oppoſite, whorled, or compound. *Flower-ſtalks* moſtly axillary, either ſimple, aggregate, or forked. *Calyx* in four or five deep ſegments. *Petals* four or five. *Stamens* almoſt always twice as many as the petals; their filaments often peculiar in ſtructure, with ſome ſort of appendages; the anthers not always terminal, ſometimes ſupported on a partial ſtalk. *Style* ſimple, connected with the inner angle of each cell of the germen, either at the ſummit or baſe. *Capsule* of four or five cells, each lined with a membranous or horny, more or leſs elaſtic, tunic, ſerving to ſcatter the *ſeeds*. Moſt of the flowers are regular, *Diſſamnus* being perhaps the only exception. It is an obſervation of our learned friend Mr. Correa, that every natural order ſeems to afford one genus, at leaſt, with an irregular flower.

Our *ZIERIA*, Tr. of Linn. Soc. v. 4. 216, belongs to this order, and we truſt will appear, in its proper place, hereafter. So likewiſe does *BORONIA*, which, having been accidentally omitted by the Rev. Mr. Wood, in vol. v. we ſhall here deſcribe.

*BORONIA* was ſo named, by the writer of the preſent article, in memory of his faithful ſervant and friend Francis Borone, born at Milan, April 6, 1769, who devoted himſelf to botany with an ardour, which his ſingular turn for obſervation, and acutenefs of diſcrimination, even with regard to the technical characters of plants, promiſed to render eminently advantageous to the ſcience. This ardour induced him to viſit Sierra Leone, as aſſiſtant to Dr. Adam

Afzelius, with whom he returned, rich in diſcoveries and information, in the autumn of 1793. The next year he attended the late profeſſor Sibthorp to Greece, and unfortunately died, by an accidental fall, at Athens, in October, 1794.—Sm. Tracts, 287. Poir. in Lamarek Dict. v. 8. 503.. Ait. Hort. Kew. v. 2. 348.—Clafs and order, *Oc-tandria Monogynia*. Nat. Ord. *Rutaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, in four deep, equal ſegments, permanent. *Cor.* Petals four, equal, alternate with the calyx and much longer, ſeſſile, withering. Nectary a glandular ring, ſurrounding the baſe of the germen. *Stam.* Filaments eight, ſhorter than the corolla, inſerted into the receptacle, alternately oppoſite to the petals and calyx, flat, tapering, fringed, terminating variously, four of them a little the ſhorter; anthers of two cells, roundiſh, incumbent, inſerted on the inſide below the ſummit of each filament. *Piſt.* Germen ſuperior, ſtanding on the nectary, conical, with four furrows: ſtyle vertical, ſhort; ſigma roundiſh, ſmooth, with four notches. *Peric.* Capsule of four diſtinct lobes, ſoon ſeparating, compressed, each of one cell, and two equal valves, lined with a bivalve elaſtic tunic. *Seeds* one or two, oblong, compressed, ſmooth, poliſhed.

Elf. Ch. Calyx in four deep ſegments. Petals four. Anthers ſtalked, below the ſummit of the filaments. Style terminal, very ſhort. Stigma capitate. Capsule of four compressed lobes. Seeds with an elaſtic tunic.

Sect. 1. *Leaves compound.*

1. *B. pinnata*. Hawthorn-ſcented *Boronia*. Sm. Tr. 290. t. 4. Ait. n. 1. Andr. Repof. t. 58. Venten. Malmaif. t. 38. Poir. n. 4. — Leaves pinnate, entire, ſmooth. Flower-ſtalks axillary, forked. Filaments obtuſe and glandular at the ſummit.—Found in the neighbourhood of Port Jackson, New South Wales. Firſt raiſed in England by Meſſrs. Lec and Kennedy in 1794. It proves a favourite, but not common, green-houſe ſhrub, flowering throughout the ſpring, and much admired for the beauty as well as ſcent of its flowers, which laſt reſembles hawthorn, approaching to *Heliotropium peruvianum*. The plant is ſmooth, ſhrubby, two or three feet high, with many roundiſh, reddiſh, leafy branches. *Leaves* oppoſite, rarely three together, without *ſtipulas*, of from three to five pair of ſeſſile, lanceolate, pointed, entire *leaflets*; the terminal one rather ſmaller than the reſt; the common ſtalk jointed, channelled, ſlightly winged, ſmooth. *Panicles* axillary, forked, ſmooth, with ſquare ſtalks, ſwelling upward. *Bractææ* ſmall, thick, oppoſite, acute. *Calyx* reddiſh. *Corolla* of a delicate pink. *Filaments* fringed with white woolly hairs to the very top, which terminates in a blunt glandular body, ſometimes ſlightly hairy alſo, riſing above the *anther*, whoſe ſtalk is curved downwards, over the *ſigma*. *Germen* ſmall, with a hairy *ſtyle*. *Seeds* ſolitary, black, in a white, poliſhed, rigid, elaſtic tunic. The dried *petals* retain ſomewhat of an acid taſte.

2. *B. alata*. Wing-ſtalked *Boronia*. Sm. Tranſ. of Linn. Soc. v. 8. 283.—Leaves pinnate, crenate; their common ſtalk hairy. Flower-ſtalks forked. Filaments obtuſe. Anthers nearly terminal.—Gathered by Mr. Menzies, at King George's ſound, on the weſt coaſt of New Holland. Rather larger, and more handſome, than even the preceding. The *branches* are hairy, as well as the under ſide of the common *footſtalks*, eſpecially at their joints. Theſe ſtalks have alſo a more dilated wing, reſembling *Fagara* in that reſpect. *Leaflets*, moſtly five pair, broad, elliptical, revolute, and crenate, with a hairy rib beneath. *Panicles* axillary, but all crowded about the tops of the branches, hairy, with fringed *bractææ*. *Flowers* larger than in *B. pinnata*; their dried petals with an opaque whitenefs

on the upper side, reddish-brown beneath. *Filaments* fringed all the way up, each terminating in a round knob, nearly on the top of which stands the capillary stalk bearing the *anther*.

3. *B. pilosa*. Hairy Boronia. Labill. Nov. Holl. v. 1. 97. t. 124. Poiret n. 1.—Leaves pinnate; leaflets linear-lanceolate, hairy, entire. Flowers solitary, axillary, and terminal, on stalks longer than the leaves.—Native of the cape of Van Diemen. *Labillardiere*. A smaller shrub than the two preceding, being only from nine to eighteen inches high. *Leaflets* from five to eleven, small and narrow, each about half an inch long; their stalks jointed, not winged. *Flowers* erect, about half the size of *B. pinnata*, solitary, on simple stalks, bearing two pair of awl-shaped *bractæas*. *Filaments* fringed, each with a round hairy head, beneath which the capillary footstalk of the *anther* is inserted.

4. *B. tetrandra*. Tetrاندrous Boronia. Labill. Nov. Holl. v. 1. 98. t. 125. Poiret n. 2.—Leaves pinnate; leaflets obtuse, smooth. Flowers solitary, axillary, on short recurved stalks. Four of the stamens awl-shaped, without anthers.—Gathered by the same botanist in Lewin's land, on the fourth coast of New Holland. This shrub is a cubit high and hairy, except the *leaflets*, which are of a very narrow obovate figure, obtuse and entire, about the size and number of the last. *Flowers* drooping, on short axillary stalks. Four of the *filaments*, opposite to the petals, are somewhat club-shaped, and bear the *anthers* on stalks below the summit; the rest, opposite to the *calyx*, are awl-shaped, rather longer, destitute of *anthers* or their stalks.

SECT. 2. *Leaves simple*.

5. *B. ferrulata*. Rose-scented Boronia. Sm. Tr. 292. t. 5.—Leaves rhomboid, acute; unequally ferrated in the upper part. Flower-stalks aggregate, terminal. *Filaments* heart-shaped and hispid at the summit.—Gathered near Port Jackson, New South Wales, by John White, M.D., to whom we are obliged for specimens and coloured drawings. A very elegant, smooth, much branched *shrub*, four feet high, not yet introduced into our green-houses, though few can be more worthy of cultivation. The *leaves* are opposite, numerous, rather crowded, hardly an inch long, somewhat oblique, entire, and tapering towards the base, sharply ferrated or toothed above; smooth on both sides, minutely dotted, with scarcely any traces of ribs or veins; their colour often purplish; their flavour approaching to that of turpentine. *Flowers* of a beautiful red, many together, in terminal corymbose clusters; their size rather exceeding that of the first species, and their scent said to resemble the fragrance of a rose. The *filaments* are red, fringed with pale hairs chiefly at the base, each terminating in a globular, emarginate knob, covered with white prominent hairs, and largest in the four longer stamens. The *anthers* stand, each on a deflexed stalk, below this knob. *Style* very short. *Seeds* two in each elastic tunic.

6. *B. crenulata*. Small-leaved notched Boronia. Sm. Transf. of Linn. Soc. v. 8. 284.—Leaves obovate, with a small point, finely crenate. Stalks single-flowered, axillary, and terminal. *Filaments* obtuse and glandular at the summit.—Gathered at King George's sound, by Mr. Menzies, with the second species. This appears at first like a slender delicate variety of the *ferrulata*, the *leaves* being about one-third the size of that species; but they are obovate, minutely crenate, not sharply toothed. The *flowers* essentially differ, being much smaller, axillary, as well as terminal, and all solitary, on bracteated angular stalks, shorter than the leaves. *Calyx* fringed. *Filaments* densely fringed throughout, obtuse, but not inversely heart-shaped, at the top, neither are they bristly, though glan-

dular, there; below the summit they are tumid and inflexed; and the footstalks of the *anthers* are nearly terminal.

7. *B. denticulata*. Narrow-leaved toothed Boronia. Sm. Transf. of Linn. Soc. v. 8. 284.—Leaves linear, toothed. Flower-stalks corymbose. *Filaments* obtuse and glandular at the summit.—Found by Mr. Menzies with the last. A branched, smooth, erect shrub, with longer, and much narrower, *leaves* than in any other known species of this genus, their margins regularly, and rather strongly, but obtusely, toothed; their base tapering down into a sort of footstalk. *Flowers* in axillary or terminal smooth corymbs, with small deciduous *bractæas*. *Calyx* smooth. *Petals* of a pale rose-colour, with a dark red rib, their size not much above half that of the *B. pinnata*. *Filaments* but slightly fringed, their summits obtuse and glandular, but not hairy. *Anthers* on lateral horizontal stalks.

8. *B. parviflora*. Pale-flowered Boronia. Sm. Tr. 295. t. 6.—Leaves obovate-lanceolate, obscurely crenate. Stalks aggregate, terminal, single-flowered. *Filaments* oblong and glandular at the summit.—Gathered near Port Jackson, by Dr. White, who sent us specimens and drawings in 1795. A smooth erect shrub, a foot or more in height, most branched and leafy at the top. *Leaves* obovate, or elliptic-lanceolate, opposite, as in all the preceding species of the present section, hardly an inch long, slightly crenate, chiefly towards the end, smooth dotted, veinless, a little aromatic. *Flower-stalks* smooth, simple, club-shaped, three together at the summit of each branch, with two axillary ones occasionally from the adjoining pair of leaves. Sometimes one or two leafy branches are extended beyond the inflorescence. *Bractæas* two or four, ovate, concave, smooth, at the common base of the stalks. *Flowers* small. *Calyx* purplish, half as long as the *petals*, which are ovate, pointed, pale bluish-coloured, with a red mid-rib. *Filaments* pink, fringed with white hairs, and terminating in an oblong, obtuse, small, slightly glandular, but not hairy, appendage, below which the *anther* projects laterally, on a horizontal stalk.

9. *B. pilonema*. Single-flowered Boronia. Labill. Nov. Holl. v. 1. 98. t. 126. Poiret n. 3.—Leaves elliptic-oblong, entire. Stalks terminal, solitary, single-flowered, without *bractæas*. *Filaments* smooth, their summit very short.—Found by Labillardiere, at cape Van Diemen. The *root* is knotty at the summit, producing several upright, simple, round, rather shrubby, *stems*, about half a foot high. *Leaves* opposite or three together, dotted, not an inch long, entire, acute, without rib or veins. *Flower-stalks* erect, swelling upwards, longer than the leaves, naked. *Flowers* about the size of the last. *Calyx* smooth, nearly as long as the *petals*. *Filaments* awl-shaped, smooth, simple, their minute points hardly extended beyond the insertion of the little stalk of the *anther*, which however is marginal, or lateral. The author suspected this plant to be very nearly related to the last, from which nevertheless he rightly distinguishes it by the solitary *flowers*, unaccompanied by *bractæas*, and the smooth *stamens*, whose points scarcely project above the spot where the *anther* is inserted, so that the latter stands above the *filament*, like a little hat, or cap; a circumstance perhaps alluded to in the name. The habit of this species, particularly the *root*, seems most to resemble the following.

10. *B. polygalifolia*. Milkwort-leaved Boronia. Sm. Tr. 297. t. 7.—Leaves linear-lanceolate, entire. Stalks axillary, solitary, single-flowered, much shorter than the leaves. *Filaments* hairy, their summit short and blunt.—Native of the neighbourhood of Port Jackson. The *root* is woody and knotty like the last, throwing up many *stems*, which

which are simple and leafy, as in that species, and the same height, but appear to be herbaceous rather than shrubby. *Leaves* mostly opposite, very rarely alternate, sometimes three together, almost sessile, an inch or more in length, acute at each end, entire, dotted, with one central rib; their under side palest. *Flower-stalks* erect, club-shaped, not a quarter the length of the leaves, angular, with a pair of small *bractes* about the middle. *Calyx* small, green, smooth. *Petals* five times as long as the calyx, rose-coloured, tipped with deeper crimson. *Filaments* pale, fringed to the top, obtuse, though scarcely extended beyond the point where the stalk of the drooping *anther* is laterally inserted. *Style* about as long as the *germen*, firmly attached to its top, so as to split into four parts with the separating cells of the fruit. *Seeds* solitary. The various distribution of the *leaves* in this species is peculiar to it. The *stems* are very rarely branched.

RUTE, in *Geography*, a town of Spain, in the province of Cordova; 5 miles S. of Lucena.

RUTENI PROVINCIALES, in *Ancient Geography*, a people of Gallia Narbonensis, according to Pliny. Cæsar (Bell. Gall. l. vii. c. 7.) mentions them. These people inhabited the territory to the left of the Tarn.

RUTGERS, JOHN, in *Biography*, an able critic and negotiator, was born of an ancient family at Dordrecht, in 1589. He received a part of his early education under Gerard Vossius, and in 1605 was sent to Leyden, where he resided with Dominic Baudius. Having completed his course, he travelled into France, and took the degree of licentiate in law at Orleans. While at Paris, he printed, at the office of Robert Stephens, an edition of Horace, with notes; which was afterwards reprinted by Burmann, at Leyden, in 1699. When he returned to Holland, he accepted the invitation of the Swedish ambassador to accompany him to Sweden, where Gustavus Adolphus, in 1614, conferred upon him the title of his counsellor. He was, after this, employed three times as envoy from that prince to Holland upon very important affairs, in which he acquitted himself with great credit, and quite to the satisfaction of his majesty, who ennobled him in 1619. He visited Bohemia, Denmark, and several German courts, in the same quality; and lastly he resided at the Hague, as minister from Gustavus to that republic, where he died in 1625, at the age of 36. He had published in 1618 six books, entitled "Varie Lectiones;" and after his death, Heinsius published his Latin poems in conjunction with his own.

RUTH, in *Biblical History*, a sacred book of scripture, admitted into the canon, and placed in our bibles between the book of Judges and those of Samuel, as being the sequel of the former and an introduction to the latter. St. Jerome informs us, that the Jews added it to the book of Judges, because the transactions which it records happened in the time of the judges of Israel (Judges, ii. 1.); and several of the ancient fathers make but one book of the Judges and Ruth. But the modern Jews place in their bibles, after the Pentateuch, the five megilloth, viz. the Song of Songs, Ruth, the Lamentations of Jeremiah, Ecclesiastes, and Esther. Ruth is sometimes placed the first of the five, sometimes the second, and sometimes the fifth.

The scope of the author of this book is to relate the genealogy of David; and hence it has been conjectured, that the first book of Samuel was composed by the same author; in which book he could not conveniently place the genealogy of David, and he therefore chose to give it by itself. The writer observes, at the beginning of his work, that the history he proposed to relate happened when the

judges governed Israel; and, therefore, they ceased to govern it when he wrote. He also speaks of David at the end of his book; which shews, that the earliest period that can be assigned to it must be the time of David. Besides, there are two modes of expression in it, which occur only in the books of Samuel and of the Kings. The first is, "The Lord do so to me, and more also," Ruth, i. 17. Compare 1 Sam. iii. 17. xiv. 44. xx. 23. 2 Sam. iii. 9. 35. xiv. 13. 1 Kings, ii. 23. xix. 2. xx. 10. 2 Kings, vi. 31. The second phrase is, "I have discovered to your ear," for "I have told you," Ruth, iv. 4. Compare 1 Sam. xx. 2. 2 Sam. vii. 27. The canonicalness of this book was never disputed. Ruth the Moabitess occurs in the genealogy of our Saviour, Matt. i. 5.

Ruth had married the son of Elimelech and Naomi, who had settled for some time in Moab; but being desirous of returning to Bethlehem, her own country, after having lost her husband and two sons, was accompanied by her daughter-in-law Ruth. This event happened, according to Usher, about 120 years after the time of Joshua. When Naomi came to Bethlehem, Ruth went to the fields in order to glean for their support; and by chance entering the field of a rich citizen of Bethlehem, named Boaz, who was related to Elimelech, her father-in-law, received from him civilities, which indicated his affection for her. In process of time, Ruth became the wife of Boaz, by whom she had a son called Obed, who was father to Jesse, and grandfather to king David. Such is an outline of the history contained in the book of Ruth.

RUTHE, in *Commerce*, a long measure at Amsterdam, which is equal to 13 feet, or 143 inches, the Amsterdam foot being = 11½ inches; the Rhineland foot of 12 inches being = 12½ English inches. At Berlin the ruthe is = 12 Rhineland feet = 148½ English inches. At Hamburg the ruthe or perch is of two sorts: one is 7 ells, or 14 feet; the other 8 ells, or 16 feet, Hamburg measure. The Rhineland ruthe (12 Rhineland feet) is 13½ Hamburg feet, or 12¼ English feet. A Hamburg mile contains 2000 Rhineland rutes, or 8244 English yards: hence 14½ fuch miles answer nearly to a degree of the meridian, and 16 Hamburg miles to 75 English miles. A scheffel of corn-land contains 200 square rutes, each 256 Hamburg square feet, which gives 166 English square perches, or 1 acre 6 perches. A morgen or acre of land contains 600 square rutes, each ruthe being 196 Hamburg square feet, which equal 2 acres 6½ perches, English measure. See MEASURE. Kelly's Un. Camb.

RUTHERFORD, in *Geography*, a county of Morgan district, in North Carolina, bounded N. by Burke, and S. by the state of South Carolina. It contains 13,202 inhabitants.

RUTHERFORD, the capital of the above county, which has a court-house, gaol, and a few houses.

RUTHERFORTH, THOMAS, in *Biography*, was born at Papsworth-Everhard, in Cambridgeshire, in 1712. Having passed through the elementary parts of his education, he was entered at St. John's college, in the university of Cambridge, where he took his degrees in the arts, and obtained a fellowship in the college. He was afterwards appointed regius professor of divinity in the university, and created D.D. Being attached to, and well versed in, mathematics and natural philosophy, he was elected a fellow of the Royal Society, and was afterwards appointed a chaplain to his royal highness the prince of Wales. In the church he was rector of Barley in Hertfordshire, and of Shenfield in Essex, and an archdeacon. He died in October, 1771, having nearly completed his 59th year. He was author of

a thin quarto in Latin, entitled "Ordo Institutionum Physicarum in privatis Lectionibus," of which the second edition was published at Cambridge in 1756; also of "A System of Natural Philosophy," in 2 vols. 4to., which for many years was held in high estimation; "Institutes of Natural and Political Law," being the substance of a course of lectures on Grotius, read in St. John's college in Cambridge, in 2 vols. 8vo. 1756; "A Letter to Dr. Middleton, in defence of Bishop Sherlock's Discourse on Prophecy," and divers other theological works. Dr. Ruthersforth communicated to a philosophical society at Spalding, a curious correction of Plutarch's description of the instrument used to renew the vestal fire, as relating to the triangle with which the instrument was formed.

RUTHERGLEN, or RUGLEN, in *Geography*, a royal borough and market-town in the lower ward of the county of Lanark, Scotland, is situated on the south bank of the river Clyde, at the distance of 2½ miles S.E. from Glasgow, and 9 miles W. from Hamilton. It is a town of high antiquity, and was constituted a royal borough by king David I., whose charter was subsequently confirmed by his successors, king Robert Bruce, James V., and James VI. At that period the river Clyde was much deeper in the lower part of its course than at present, and Rutherglen was not only a considerable sea-port, but was in fact the first mercantile town in the valley of Clyde. When the city of Glasgow, now the emporium of Scottish commerce and manufactures, consisted but of a few private houses attached to the cathedral, this town was comparatively a busy spot, whose inhabitants devoted themselves to civil and commercial employments. Glasgow, indeed, appears even to have been within the bounds, over which the corporation of Rutherglen claimed jurisdiction; for a charter is yet extant, bearing date in 1226, whereby a grant is made to the bishop of Glasgow, and his successors, that no toll nor custom shall be levied in that city by the inhabitants of Rutherglen. All the mercantile importance of this place, however, is now lost, and it is also reduced in extent and population. It still retains, nevertheless, all the privileges of a royal burgh, and is governed by a provost, two bailies, a dean of guild, and fifteen councillors, who are elected annually at Michaelmas. The principal branch of trade carried on here is the weaving of mullins for the Glasgow manufacturers. The market-day is Wednesday, weekly; and there are, besides, six annual fairs, famous for the sale of horses. Since the union, this burgh has joined with Glasgow, Renfrew, and Dumbarton, in sending a representative to the British senate.

The town of Rutherglen consists chiefly of one principal street, and a lane, called the Back-Row, both lying parallel in a direction nearly east and west. The main street, which is very straight and well paved, extends about half a mile in length, and is about 100 feet in breadth. From both sides of it, several lanes go off; and at the distance of about 150 yards to the southward is another lane, known by the name of Din's-Dykes, which is characterized with an indelible mark of opprobrium from the following circumstance. The unfortunate Mary, queen of Scots, having viewed the battle of Langside from an eminence near this town, no sooner saw her army defeated than she fled to the south. Din's-Dykes unfortunately lay in her way. Two rustics, who were at that instant cutting grass close by, seeing her majesty flying in haste, rudely attempted to stop her, and threatened to cut her to pieces with their scythes if she presumed to proceed a step further. Neither beauty, nor even royalty itself, can at all times secure the unfortunate, when they are assailed by the unfeeling or re-

vengeful. Relief, however, was luckily at hand, and her majesty was rescued from her barbarian oppressors.

The church of this town, which is the only public edifice worthy of notice, is very ancient, and is in a style of architecture superior to most churches in Scotland. But what renders it particularly interesting is the circumstance of its having been the scene of two transactions, in which the fate of sir William Wallace, and of the kingdom of Scotland, were deeply concerned. It was within the walls of this church that peace was concluded between England and Scotland in the year 1297, and it was here also that sir John Monteith contracted with the English to betray the greatest of Scottish heroes.

Rutherglen, in ancient times, was a place of strength, and had a castle attached to it, which was considered to be one of the most important Scottish fortresses. In the dispute between Bruce and Baliol for the possession of the throne, it fell, with many others, into the hands of the English. It was besieged by Robert Bruce in 1309; but he appears to have been compelled to abandon the enterprise by the approach of an English army. In 1313, however, it was taken by Edward Bruce, the king's brother; and seems ever after to have belonged to the Scotch. This castle was kept in good repair till a short time after the battle of Langside, when it was burnt by the orders of the regent, Murray, out of revenge against the Hamilton family, in whose custody it then was. One of the principal towers was, however, afterwards repaired, and having been enlarged by some modern improvements, became the seat of the Hamiltons of Elliston, lairds of Shawfield. At length, on the decline of that family, it was for about a century wholly neglected, and, by frequent dilapidations, was soon levelled with the ground. Its site is now converted into a kitchen-garden; but many of its sculptured stones may be seen built into the walls adjoining the town.

In Rutherglen the custom of riding the marches of the borough is still observed. On the day appropriated to this purpose, the magistrates and council assemble at the cross, whence they proceed, in martial order, with drums beating, &c. round the boundaries of the royalty, to see if any encroachment has been made. These boundaries are distinguished by march-stones set up at small distances from each other, which are shaped at the top in the form of a man's head; but the lower part is square. This peculiar form was originally designed to represent the god Terminus, of whom they are so many rude images. Every new burghess is bound to provide a march-stone at his own expence, and to cut upon it the initials of his name, and the year in which it is set up. It has been a custom, time out of memory, for the riders of the marches to deck their hats and drums with broom, and to combat with one another at the newly-erected stone, out of respect perhaps to the deity whose image they had set up, or that they might the more firmly impress on their minds the precise boundary of that place. This ceremony has of late been deferred till the company return to the cross, when the broom engagement commences with great fury, and lasts as long as the weapons will endure. Rutherglen is likewise famous for the singular custom of baking, what are called, four cakes, previous to St. Luke's fair. The operators are women only, and they seldom begin till after sunset, and a night or two before the fair. A large space of the house is marked out by a line drawn upon it. The area is considered as sacred, and if passed by any of the by-standers, he or she incurs the penalty of a fine, which is expended in drink for the use of the company. This hallowed spot is occupied by six or eight women, all of whom, except the toaier, feat

feet themselves on the ground in a circular form, having their feet turned towards the fire. Each of them is provided with a baking-board about two feet square, which they hold on their knees. The person who toasts the cake, which is done on an iron-plate, suspended over the fire, is called the queen or bride, and the others her maidens. She nearest the fire on the east is named the todler, and her companion on the left-hand the hodler. The remainder have arbitrary names given them by the bride. The business is commenced by the todler, who takes a ball of the dough, forms it into a small cake, and then casts it on the baking-board of the hodler, who beats it out a little thinner, and then throws it on the board of her next neighbour, and thus it goes round from east to west till it comes to the toaster, by which time it is as thin and smooth as a sheet of paper. The first cake cast on the girdle is usually named as a gift to some well-known cuckold, from a superstitious notion that thereby the rest will escape that mischance. As the whole operation is performed by the hand, considerable noise is made; but as the bakers generally beat time to some air sung by one or more of the company, it is far from being disagreeable. Great dexterity is requisite in the performance of this custom, particularly in throwing the cakes from one board to another, without ruffling or breaking them; and as the toasting requires great skill, the most experienced person is always chosen for that part of the work. One cake is sent round in quick succession after another, so that none of the individuals engaged are suffered to be idle. The whole is a scene of activity, mirth, and diversion. There being no account, even by tradition, of the origin of this custom, it is presumed to be very ancient, and probably took its rise in the days of paganism, as it is fraught with several of the sacred rites peculiar to heathen worship; such as the leavened dough, the mixing with sugar and spices, the consecrated ground, &c.; but the particular deity for whose honour these cakes were first made, is a point of difficult solution. According to the population census of 1811, the borough and parish of Rutherglen contain 756 houses, and 3529 inhabitants. The History of Glasgow and its Suburbs, by James Denholm, 1 vol. 12mo. Glasgow, 1798. Beauties of Scotland, vol. iii. 8vo. Lond. 1806.

RUTHIN. See RUTHYRN.

RUTHSBOROUGH, a village in queen Anne's county, Maryland, on Tuckahoe creek; 6 miles S.E. of Centerville.

RUTHWELL, a market-town and parish in the county of Dumfries, Scotland, is situated on the northern bank of the Solway frith. The town, which stands on the high road from Port-Patrick to Carlisle, was formerly a long straggling place, but has of late years been much improved, and almost entirely rebuilt, chiefly at the expence of the earl of Mansfield, who is proprietor of the greater part of the parish. It is a burgh of barony, and has the privileges of a weekly market, and several annual fairs. The parish extends about six miles along the shore of the Solway frith, and is nearly three miles in breadth. In virtue of an ancient charter from one of the kings of Scotland, all the inhabitants were entitled to manufacture salt duty free; consequently a large quantity of that article was formerly made here; and the trade is still followed by many persons, though the exemption from duty has been discontinued since the union. About forty years ago a singular road was discovered leading through a deep morass. It was formed of strong oak planks, eight feet in length, fastened down by stakes driven through the boards into the earth. At the time it

was thrown open, it lay six feet beneath the surface of the earth.

The church of Ruthwell, one of the oldest ecclesiastical buildings in Scotland, was formerly remarkable for an ancient obelisk which stood within its walls, and fragments of which are still visible in the church-yard. This monument was demolished by order of the General Assembly in 1644, under pretence of its being an object of superstition among the vulgar. When entire, according to Pennant, it measured about twenty feet high, exclusive of pedestal and capital, and was of a square form, but the sides were of unequal breadth. Two of these were ornamented with foliage and figures of animals, and had Runic inscriptions round the margin. On one of the broader sides was a very rude figure of our Saviour, and beneath were two other figures, one bearded, and the other not, designed to represent some of the apostles. The opposite side also displayed a figure of the Saviour, with Mary Magdalen washing his feet. These sculptures, says the author above-mentioned, were probably "the work of different times and nations; the first, that of Christian Saxons, the other of the Danes, who either found those sides plain, or, defacing the ancient carving, replaced it with some of their own." In the cemetery is a monument to the memory of Mr. Gawin Young, the Scottish vicar of Bray, who was ordained minister of this parish in 1617, and maintained his post for fifty-four years, notwithstanding the many changes from Presbyterianism to Episcopacy, and from Episcopacy to Presbyterianism, which occurred during that revolutionary period. The inscription has, among others, these words:

"Far from our own; amidst our own we ly;  
Of our dear bairns thirty and one us by."

Within this parish stands Comlogran castle, an ancient mansion, belonging to the earl of Mansfield. It is surrounded by extensive parks and plantations, and commands a fine view of the Solway frith, and of the adjacent country. There are likewise some remains of an ancient castle at Cockpool.

According to the population census of 1811, Ruthwell parish contained 231 houses, and 1184 inhabitants. Pennant's Tour in Scotland, vol. i. 4to. Lond. 1776. Carlisle's Topographical Dictionary of Scotland, 4to. 1813.

RUTICILLA, in *Ornithology*, a species of *Muscicapa*; which see.

RUTICILLA, the *Red-Start*; which see. See also *MOTACILLA Phœnicurus*.

RUTIDEA, in *Botany*, a genus so named by Decandolle, from *ῥυτίς, ῥυτίδος, a wrinkle*, alluding to the ruggedness of its seeds. *Annales du Muséum d'Hist. Nat.* v. 9. 219. *De Theis*.

RUTIGLIANO, in *Geography*, a town of Naples, in the province of Bari; 8 miles S.W. of Monopoli.

RUTILE, in *Mineralogy*, *Titanic Rutile* of Brongniart, an oxyd of titanium: it is of a dark blue-red colour, inclining to brown, with a degree of metallic splendour: the longitudinal fracture is foliated; the cross fracture conchoidal and unequal. It is opaque or slightly translucent, and sometimes sufficiently hard to scratch quartz. The specific gravity is from 4.18 to 4.24. Rutile is infusible by the blowpipe, but with the addition of borax it melts into a yellow glass. It is found crystallized: the primitive form of the crystals is a right-angled prism. Sometimes two crystals are united by their extremities, forming a kind of twin-crystal. It also occurs in extremely minute capillary crystals,

crystals, which are either divergent or reticulated, but sometimes single, and are imbedded in quartz and rock-crystal. From the analysis of Klaproth, it appears to be a pure oxyd of titanium. This mineral is found near Limoges in France, in Hungary, at St. Gothard in Switzerland, on the Carpathian mountains, near Burgos in Spain, in Siberia, on the summit of Sierra de Avilla, in New Granada in South America, and in South Carolina in North America.

**RUTILITE**, called by Klaproth *Sphen*. Its colour is a brown, inclining to red, yellow, grey, or black. It is found both crystallized and amorphous. The crystals are small, oblique, four-sided prisms, which are acutely bevelled at both extremities, but are sometimes terminated by tetrahedral pyramids. The longitudinal fracture is radiated or foliated, the cross fracture flatly conchoidal, passing into even. The lustre is glistening, or faintly glimmering; it is more or less translucent on the edges. Rutilite scratches glass, is very brittle, and nearly infusible by the blowpipe, without the addition of borax or an alkali. The specific gravity is from 3.1 to 3.5. According to Klaproth it consists of

Oxyd of titanium	-	-	35
Silex	-	-	35
Lime	-	-	33

It is found at Passau, in the district of the Inn, in a rock composed of felspar, hornblende, and quartz. It also occurs in several Norwegian mines.

**RUTILIUS, NUMATIANUS**, in *Biography*, a Latin poet, probably a native of Toulouse, and advanced to high employments at the Roman court, was a military tribune, and about the year 414 A. D. was prefect of Rome. The empire at this time, as we have seen in the article **ROME**, was over-run by the Visigoths, under the furious Alaric and his successors; and Rutilius, for the purpose of succouring his distressed native country, took a journey from Rome to Gaul, of which he wrote a description in elegiac verse. It consisted of two books, of which the latter is lost. The work gives a favourable impression of the writer, who was a Pagan, though it has been greatly censured by Catholic authors, on account of the following remarks which it contains on the monks of the island of Capraria. "The whole island," says Rutilius, "is filled, or rather defiled, by men who fly from the light. They call themselves monks, or solitaries, because they choose to live without any witnesses of their actions. They fear the gifts of fortune, from the apprehension of losing them; and lest they should be miserable, they embrace a life of voluntary wretchedness. How absurd is their choice; how perverse their understanding, to dread the evils, without being able to support the blessings, of the human condition. Either this melancholy madness is the effect of disease, or else the consciousness of guilt urges these unhappy men to exercise on their bodies the tortures which are inflicted on fugitive slaves by the hand of justice." For these and some other remarks on the Jewish sabbath as a commemoration "Lassati Dei," Rutilius and his adherents are styled, by his commentator, Barthius, *rabiosi canes diaboli*; but Tillemont remarks, that the unbelieving poet praises where he means to censure. The verse of Rutilius is said to be more elegant than the common standard of the age; and though the subject does not admit of poetry, he displays much taste and ingenuity. The "Itinerarium" was discovered in 1494 at a monastery, and has been several times printed. The best editions are those of 1582, and 1687. It is inserted in Burmann's "Poetæ Minores," and in Mattaire's "Corpus Poetarum."

**RUTILUS, ROACH**, in *Ichthyology*, a species of *Cyprinus*; which see.

**RUTILUS Lator**, a name given by many authors to the fish called in English *rud*, or *fin-scale*, and *rubellus*. See **CYPRINUS Erythrophthalmus**.

**RUTINIUM**, in *Ancient Geography*, a town of the island of Albion, upon the route from the Portus Rutupæ, between Mediolanum and Uriconium in the Itinerary of Antonine. Camden, Gale, and Baxter agree in opinion, that Rutinium was situated at Rowton castle; but Mr. Horsley is positive, that it was really at Wem, on the banks of the river Roden.

**RUTKIN**, in *Geography*, a town of Bohemia, in the circle of Koningratz; 8 miles E. of Gitschin.

**RUTLAM**, a town of Hindoostan, in the Malwa country; 48 miles W. of Ougein. N. lat. 23° 23'. E. long. 74° 58'.

**RUTLAND, First Duke of**, in *Biography*. The words of the opera of Tamerlane, written by Nicola Haym, and set by Handel in 1724 for the Royal Academy of Music, were dedicated to the duke of Rutland, not only as one of the directors of the Royal Academy of Music, and a liberal patron of science, but as a nobleman who, by study and application, had rendered himself a most intelligent judge both of the theory and practice of the art of music. And it is well known that the first duke of Rutland was an excellent performer on the violin; that his grace brought Carbonelli hither from Italy, when he returned from his tour through that country; and that the solos which this musician dedicated to him, were composed expressly for his use.

**RUTLAND**, in *Geography*, one of the Andaman islands, in the East Indian sea. N. lat. 11° 24'. E. long. 92° 27'.

**RUTLAND**, a county of Vermont, bounded N. by Addison county, E. by Windfor, S. by Bennington, and W. by New York. This county is watered by Otter creek and other streams. It abounds with lakes or ponds stored with fish; the principal are lakes Bombazan and St. Austin, the former in Hubbardton and Cattleton, and the latter in Wells. It contains 25 townships, and 29,486 inhabitants. In this county are 14 forges, 3 furnaces, and a sitting-mill.—Also, a post-town of Vermont, the capital of the above county, situated on Otter creek; 55 miles from its mouth in lake Champlain, 45 miles W. by N. from Windfor. It contains a congregational church, a court-house, and 2379 inhabitants. The mean heat of this place is 43°.6, the least 21°, and the greatest 92°. Durable crucibles are wrought of the pipe-clay found here. N. lat. 43° 34' 30". W. long. 72° 50' 10".—Also, a township of Worcester county, Massachusetts; 14 miles N.W. of Worcester; incorporated in 1722, and containing 1231 inhabitants. It is situated on the height of land between Connecticut river and Merrimack. The prospects from the centre of the town are extensive and delightful. It is a curious circumstance, that the water which drops from the eastern roof of a barn in this town runs to the Merrimack, and that which falls from the western side runs to the Connecticut. In this town are two considerable ponds, which furnish streams in different directions, some of which are large enough for mills.

**RUTLAND**, a post-town of Ireland, in the county of Donegal, built in one of the cluster of islands called North Isles of Arran, in the district of the Rosses. The late colonel Burton Conyngham procured a grant from parliament to establish a settlement here, as a situation peculiarly adapted to the herring fishery. This town, so called from the duke of Rutland, who was viceroy at the time, has very fine stores and accommodations for drying and salting the fish,

but,

but, like most undertakings which owe their origin to parliamentary grants, it has proved unsuccessful, and remains a monument of the folly of expecting to force trade by such means. The sum expended was 20,000*l.* by parliament, and as much more raised by mortgage on the estate of colonel Conyngham; a man who, however he might be mistaken in his calculations of advantage, was too honourable and patriotic to be suspected of an intention to mislead. Rutland is 153 miles N.W. from Dublin. N. lat. 54° 56'. W. long. 8° 18'. Journals of the House of Commons.

RUTLANDSHIRE, one of the central counties of England, is bounded on the north, north-west, west, and south-west, by Leicestershire; on the south and south-east by Northamptonshire; and on the east and north-east by the county of Lincoln. It is the smallest shire in the kingdom, extending only about 18 miles in length and 15 in breadth; its circumference being 60 miles, which gives an area of 200 square miles, or 128,000 acres. According to the parliamentary returns of 1811, it contains 3417 houses and 16,380 inhabitants.

The *history* of this county, in remote times, is so intimately connected with that of the surrounding counties, that they can scarcely be separated. Previous to the arrival of the Romans it formed part of the territories of the Coritani; and after the latter were forced to submit to the imperial authority, it was included in the province of Flavia-Cæsariensis. During the Saxon heptarchy it formed part of the kingdom of Mercia, under eighteen successive monarchs; and when the Saxon kingdoms became united into one, it seems to have belonged to the crown; as we find that Edward the Confessor bequeathed it to his queen Edith, and after her demise to Westminster Abbey. His will, which is still extant, says, "I will, that after the decease of queen Eadgith my consort, Rotelond, with all its appurtenances, be given to my monastery of St. Peter, and be surrendered, without delay, to the abbot and monks there serving God, for ever." So anxious, indeed, was the king to secure this obituary grant to the abbey, that he endeavoured to render more certain the observance of his will by a kind of anterior deed of gift, bearing date in the 25th year of his reign. This grant, however, was but of short duration, for when William the Conqueror ascended the throne, he resumed possession of Rutlandshire as crown land, and merely allowing the monastery to receive the tithes, divided it among some of his nearest relatives, and his most powerful adherents. These first Norman grantees were Robert Malet, great chamberlain of England; Gilbert de Gaunt; earl Hugh; Aubrey, the clerk, and several others. Some manors were likewise granted to the conqueror's niece Judith, afterwards countess of Huntingdon; and to Maud, countess of Albemarle, his half sister. Considerable possessions, however, were reserved to the crown; and in the reign of Edward II. he possessed the hundreds of Martinley, Alsto, and East hundred, all of which that monarch granted to the lady Margaret, wife of Piers de Gaveston, duke of Cornwall, to be held by her during the royal pleasure. The hundred of Wrangdyke was then the property of Guy de Beauchamp, earl of Warwick, but his son Thomas being a minor at his father's death, Edward gave that estate to Hugh Spencer the elder, on the pretence of its being in satisfaction of a debt due to him of 6770*l.* During those transactions, the present hundred of Oakham-Soke is never mentioned: it is therefore conjectured to have formed part of Martinley hundred.

The aspect of the country in Rutlandshire is, generally speaking, very beautiful, being much diversified by gently

rising hills, running east and west, with vallies about half a mile in breadth intervening, so that every three or four miles presents a new view to the eye of the traveller. The principal vale is that of Catmose, in the centre of the county, which Camden describes as "a pleasant and fertile valley, perhaps from Coet Maes, which signifies in British, a woody plain." On the north side of this vale the ground rises, and level with its summit a flat tract extends for several miles to the northward, forming a kind of table land, looking down upon the fertile and well-wooded plains of Leiceter, Nottingham, and Lincoln-shires. The southern district consists, in a great measure, of one widely expanded vale, mostly open land, which stretches into Northamptonshire; and on the western borders, the remains of the old forest of Liefeld are well wooded, and sink in the distance into the Leicestershire plains.

The climate of this county is generally reckoned good and healthy, but has no peculiarity demanding notice. The soil is various, but is, upon the whole, fertile. The most prevalent kind is a strong reddish loam, intermixed with keal, lying upon an under-stratum of blue clay; but almost every farm has a mixture of poor clay, hazel earth, white stony land, black clay and gravelly clay. This great variation of soils within a small space causes each sort to be much more valuable than it would be, were one kind prevalent throughout an entire lordship.

The modes of agriculture adopted here differ, as may be supposed, in some degree on the different soils, and also on the inclosed and uninclosed lands. Upon the uninclosed arable lands, except upon some of the light soils, the old course of two crops and a fallow is yet practised. On the light soil, a turnip crop is substituted for the fallow, and barley is sown instead of wheat for the ensuing crop. The second crops on both soils are peas, or peas and beans. A few farmers in the eastern district sow barley and broad clover after fallow, mowing the clover for a second year's crop, and feeding it off with sheep when it is considered as proper for a course of wheat. The farmers have an idea that winter ploughing is hurtful to the land, and consequently they lay their manure on the fallows, where it remains till the spring.

The inclosed lands consist mostly of the light soils, on limestone bases; and of the heavy red loam. These are principally under the Norfolk husbandry of four years' rotation, and without feeding off, except in the turnip crops; but another mode is likewise practised, of taking two crops of spring corn after breaking up the clover, then turnips, next barley with rye-grass and clover, after which there are three or four years' sheep-feeding, when it is broken up again for spring corn. The first of these methods is beneficial for raising a large crop of wheat, and the second is equally advantageous for sheep flock, and hence each has its warm advocates among the farmers.

Tenures in this county are various; freehold, leasehold, and copyhold, but freehold is most general. A few farmers hold their lands by leases of seven or twenty-one years' duration; but by far the greater proportion of land is held at will from year to year. Rents, in 1806, averaged about 1*l.* 1*s.* per acre, but they are now much increased. Above three-fourths of the parishes are exonerated from tithes, either by modus, or being made free. Farms differ much in size, running from 15 to 640 acres, but the large farms are few in number.

Respecting the mineralogy of Rutlandshire there is nothing worthy of notice, except that there is at Ketton "a kind of stone very proper and famous for buildings;" and in several places lime-stone, consisting of a hard and soft species,

species, and containing a great number of marine substances. The existence of chalybeate springs in different parts of the county, however, seems to prove the presence of ironstone, but that mineral has not yet been discovered, at least in any quantity.

The only rivers of note, connected with the county, are the Guash and the Welland. The former, which is popularly called the Wash, intersects the county nearly in the centre, crossing it from east to west. It takes its rise in Leicestershire, and is considered to be an excellent fishing river. The Welland also has its source in Leicestershire, and forms the boundary for many miles between this county and Northamptonshire. The other Rutlandshire streams are the Chater, which crosses the county to the southward of the Guash, and the Little Eye, or Lytelee, which bounds it on the south-west. Rutlandshire does not boast of a single lake; but it has the more important advantage of a canal, denominated the Oakham canal. This branch of a more extended line begins in the vicinity of Melton Mowbray, in Leicestershire, enters Rutlandshire near Teigh, and passes by Market Overton, Barrow, Cotmore, and Burley, until it approaches Oakham on the north side in the level of the vale of Catmose.

The roads in this county are tolerably good, but are not generally formed on a good plan, being raised too high before the materials are laid upon them, and the stones being much too large. No manufactures of any import are carried on here, owing to the deficiency of water and the scarcity of fuel. Rutlandshire may, therefore, be considered as entirely an agricultural county; and it is worthy of remark, that notwithstanding the improvements in husbandry, population has not increased during the last thirty years; while in manufacturing counties it has almost doubled itself within the same period.

Politically speaking, Rutlandshire is divided into five hundreds, *viz.* Wrangdyke, Alto, Oakham, East, and Martinley, which contain fifty-three parishes and two market towns, Oakham and Uppingham. There are no boroughs in the county, so that it is represented in parliament only by two knights of the shire. In judicial affairs it is in the Midland circuit, and in ecclesiastical jurisdiction is subject to the bishop of Peterborough. Rutland was an earldom at a very early period, and the honour was usually a branch of the royal family. It is now a dukedom in the family of Manners. This county is altogether devoid of objects of antiquarian curiosity. Beauties of England and Wales, vol. xvii. by Mr. Laird, 8vo. 1814. General View of the Agriculture of the County of Rutland, by Richard Parkinson, London, 8vo. 1808. A portion of a history of this county has been recently published by Thomas Blore, folio. This specimen is so well executed, that every lover of topographical history, as well as the inhabitants of the county in general, must regret that the whole work is not completed in the same style and manner.

RUTLEDGE, the shire-town of Grainger county, in the state of Tennessee, situated in Richland valley: it contains a few dwelling-houses, and is merely a handsome flourishing village.

RUTLINGEN. See REUTLINGEN.

RUTNAGHERI, a hill-fort of Hindoostan, in Myfore, taken in the year 1799 by the British; three miles W.S.W. of Oudeadurgam.

RUTSHA, a town of Imiretta; 38 miles N.E. of Co-tatis.

RUTTAGURRA, a town of Hindoostan, in Malwa; 30 miles E.N.E. of Bilfah.

RUTTANGUR, a town of Hindoostan, in Baglana; 25 miles N.W. of Junere.

RUTTEE, a weight used in the East Indies, one hundred of which make eighty-eight caracts. See CARACT.

RUTTENSTEIN, in *Geography*, a town of Aultria; 9 miles N.N.W. of Grein.

RUTTUNGUNGE, a town of Bengal, 47 miles S.S.E. of Nattore. N. lat.  $23^{\circ} 53'$ . E. long.  $89^{\circ} 43'$ .—Alfo, a town of Bengal; 10 miles S. of Boglipour.

RUTTUNPOUR, a circar of Hindoostan, bounded on the N. by Surgooja and Jushpour, on the E. by Gangpour, on the S. by a country unknown to Europeans, and on the E. by Goondwanah. Its chief towns are Ruttunpour, Raypour, and Dumdah. It is traversed towards the south by the river Mahanada.—Alfo, the capital of the fore-mentioned circar, in the country of Orissa; 326 miles W. of Calcutta, lying in the road from Bahar to Nagpour. N. lat.  $22^{\circ} 16'$ . E. long.  $82^{\circ} 36'$ .—Alfo, a town of Hindoostan, in Bahar; 12 miles N.W. of Durbungah.

RUTUBA, in *Ancient Geography*, a river of Italy, in Liguria, according to Pliny, lib. iii. c. 5.

RUTULI, a people of Italy, in Latium, who inhabited the country near the sea-coast. Their origin is uncertain; but it seems, according to Virgil, that at the arrival of Æneas, Turnus was their king. This prince, in his attempt to oppose the establishment of the Trojans, was killed in the combat. The Rutuli, in process of time, were often confounded with the Latins. Their capital was called Ardea.

RUTULUS, in *Roman Antiquity*, the barrier of the cavea, or place where the wild beasts used in amphitheatrical sports were shut up. It was made of iron bars, which turned upon hinges, and all at once flew open with great swiftness.

RUTUNIUM, in *Ancient British Geography*. See RUTINIUM.

RUTUPLÆ PORTUS, in *Ancient Geography*. See RICHBOROUGH.

RUTY-PUNDOC, in *Natural History*, a name given by the people of the East Indies to a peculiar species of yellow orpiment, which they find on the tops of the mountains there; and, after several calcinations, give internally in coughs and colds. The ancient Greeks used this orpiment in the same manner. We have of late run into an opinion of its being a fatal poison; but Dr. Boerhaave, in his Chemistry, affirms, on his own trials, that it is innocent and harmless. These people, who have not the use of chemistry, give us a hint of the virtues of great numbers of our own fossils, which are common also to their country. The selenitæ, fibrose tails, spars, and many other fossils, which we wholly neglect, are in common use with them, and great cures are often performed by them.

RUTZDORF, in *Geography*, a town of Brandenburg, in the New Mark; eight miles N. of Cultrin.

RUTZEN, a town of Silesia, in the principality of Wolau; 18 miles N. of Wolau. N. lat.  $51^{\circ} 37'$ . E. long.  $16^{\circ} 32'$ .

RUUN, RUNO, or *Runeholm*, an island of the Baltic, belonging, in an extensive sense, to the province of Oesel, and lying in the middle of the gulf of Riga, at the distance of 95 versts from the town of that name, and rather more than 51 versts from Oesel. It is distinguishable far off at sea by a forest of birch trees, which occupies one of its sides. It is entirely the property of the crown, and is inhabited by Swedish boors. Here is a church, to which belongs a preacher, whose congregation is small, but income very decent, consisting of the tythe of all the products of the island, together with a portion of land. In this island is  
a light-

a light-house, for the supply of which the boors are obliged to buy the fuel on the continent, the crown allowing them towards it 40 dollars. There is no farm on the island except that of the pastorate. Among the inhabitants, it is said, there are some remains of the old Livonians, who speak the Runic language, also the Ethnic, the Lettish, the Swedish, and most commonly the German and Rufs, each with facility, from their frequent intercourse with others. In the labours of the chase, and the capture of the sea-dog, they are indefatigable, by which they gain an opulent subsistence. They live in great harmony, and only intermarry among their own society. Tooke's *Russia*, vol. ii.

RUVO, a town of Naples, in the province of Bari, the see of a bishop; 5 miles S. of Trani. N. lat.  $41^{\circ} 12'$ . E. long.  $16^{\circ} 28'$ .—Also, a town of Naples, in Basilicata; 18 miles S.W. of Venosa.

RUY, a town of France, in the department of the Isere; 20 miles E. of Vienne.

RUYSCH, FREDERIC, in *Biography*, a celebrated anatomist and physician, was born at the Hague, in the month of March 1638. His father was commissary of the States-general, and descended from a family of considerable wealth and importance at Amsterdam, where they had occupied places of public trust for two centuries, until the Spanish war, which began in 1576, occasioned a great revolution in their fortunes. The celebrity of the name, however, is built upon the talents and personal merits of Frederic. He commenced his academical studies at Leyden, after being grounded in grammatical learning in his native city, and applied himself with great assiduity to the study of anatomy, botany, and chemistry, especially to the practical investigation of these sciences, having conceived an early bias to the profession of medicine. His zeal and curiosity were so much excited by the new objects which opened before him, that he allowed nothing to interfere with his labours, and at length the habit of experimental research rendered the most laborious inquiries a mere agreeable recreation. He repaired also to Francker, for the farther pursuit of his studies; but received the degree of doctor at Leyden, in 1664. Even during his pupillage at Leyden, he was applied to by Sylvius and Van Horne, to assist them in combatting the vanity of Bilsius, who came thither to exhibit his boasted method of preserving dead bodies.

After his graduation, young Ruysch returned to the Hague, where he married, and settled to heartily to the practice of his profession, as even to neglect every pursuit which had not some relation to it. In the following year, 1665, he published his treatise on the lacteal and lymphatic vessels, which contained the result of his inquiries while engaged in the dispute with Bilsius. In this work he does not deny that the existence of valves in the lymphatic had been noticed before, but he claims the honour of having first demonstrated them, and taught the method of discovering them. This ingenious tract immediately procured him reputation; and he was invited, the year after, to the chair of anatomy at Amsterdam; an invitation which he gladly accepted, on account of the great opportunities which it was likely to afford for the prosecution of his favourite researches. Anatomy, in fact, both human and comparative, henceforth constituted the principal object of his life: he spared neither time, labour, nor expence, for the attainment of his purposes; he was almost continually employed in dissection, and not only examined with the most minute exactness every organ of the human body, but devised means by which to facilitate the detection and demonstration of the different parts, and to preserve and exhibit them thus demonstrated. If he were not the discoverer of the use of injections, for the display of

vascular and other structure, he contributed, together with the suggestions of De Graaf and Swammerdam, by his own ingenuity and industry, to introduce that important practice among anatomists. His collection of injected bodies is described, indeed, as marvellous; the finest tissue of capillary vessels being filled with the coloured fluids, so as to represent the freshness of youth, and to imitate sleep rather than death. In this way he had preserved fœtuses in regular gradation, as well as young and adult subjects, and innumerable animals of all sorts and countries. His museum, indeed, both in the extent, variety, and arrangement of its contents, became ultimately the most magnificent that any private individual had ever accumulated, and was the resort of visitors of every description; generals, ambassadors, princes, and even kings, were happy in the opportunity of examining it. The czar Peter, in his journey through Holland in 1698, frequently dined at the frugal table of Ruysch, in order to spend whole days in his cabinet; and in 1717, on his return to Holland, the czar purchased it of him for 30,000 florins, and sent it to Petersburg. The indefatigable anatomist immediately commenced the labour of supplying its place by a new collection.

When we consider the advantages which Ruysch possessed, his ingenuity in devising the means of minute investigation, and the *improbable labor* by which he manufactured two collections of anatomical preparations, and investigated such a multitude of subjects, it will be expected that he must have been the author of some discoveries. He claims, indeed, and probably made many; which, however, were not all unknown to other anatomists: for his fault was a neglect of reading, which rendered him often ignorant of the discoveries of others; and therefore he sometimes gave, as new, what other writers had described. Among other parts which he investigated minutely, were the pulmonary circulation, (in which he claims the discovery of the bronchial artery,) the structure of the ear, of the brain, of the lymphatic and glandular system.

Ruysch was appointed professor of physic in 1685, a post which he filled with honour and reputation until the year 1728, when he unhappily broke his thigh by a fall in his chamber. He was also nominated superintendent of the midwives at Amsterdam, in the exercise of which office he introduced some improvements in the practice of these good women; especially the abolition of the habit of speedily extracting the placenta, which he believed to be expelled by an orbicular muscle at the fundus. He was a member of the Royal Society of London, and of the Academy of Sciences of Paris, having succeeded sir Isaac Newton, in the latter body, in 1727. In the same year he had the misfortune to lose his son, Henry Ruysch, also doctor of physic, who, like himself, was an able practitioner, well skilled in anatomy and botany, and was supposed to have materially assisted him in his publications, inventions, and experiments. This loss was the more severely felt, on the occurrence of the accident just mentioned, as it deprived him of his best assistance in completing the second collection of rarities, which he was occupied in making. His youngest daughter, however, who was still unmarried, and had been initiated into all the mysteries of his anatomical experiments, was fully qualified for the task of assistance which she now undertook, and he proceeded with his new museum; retaining his general health until the commencement of the year 1731, when he was carried off by a fever, in the ninety-third year of his age.

Ruysch was the author of many publications, several of which were controversial; for his want of reading, and consequent differences with some of the learned of his profession, led him into frequent disputes. His first work, which ori-

ginated in his defence of Sylvius and Van Horne against Bilius, was entitled "Dilucidatio valvularum in Vasis Lymphaticis et Lacteis, cum figuris æneis," Hague, 1665. His second was "Observationum Anatomico-Chirurgicarum Centuria. Accedit Catalogus rariorum in Musæo Ruyfchiano," Amst. 1691; containing some curious facts and engravings. His third publication was an answer to Bidloo, who had attacked several of his doctrines, and was entitled "Responso ad Godef. Bidloo Libellum, cui nomen Vindicium, &c." 1694. In addition to this, he published no less than fourteen controversial works, in answer to professor Gaubius, to C. Wedelius, and others, which were entitled "Epistolæ Anatomicæ Problematicæ, unâ cum Responsonibus," and were printed between the years 1696 and 1700 inclusive, and in many of which considerable acrimony appears on both sides.

In addition to these numerous tracts, Ruyfch also published a series of anatomical essays, to the number of twelve, under the title of "Theaurus Anatomicus primus, secundus, &c." between the years 1701 and 1728, containing the results of his minute investigations into the structure of the different organs and textures of the body, and, in the last, observations on the anatomy of vegetables. He published also "Theaurus Animalium," in 1710, with plates; three decades of "Adversaria Anatomico-Chirurgico-Medico," in 1717—20, and 23. And a tract "De Fabricâ Glandularum ad Boerhaavium," 1722, in answer to an attack from that celebrated professor. A collection of all his works was printed at Amsterdam in 1721, 4to. entitled "Opera omnia Anatomico-Medico-Chirurgica;" but this is necessarily less complete than the edition of 1737, in five volumes, 4to.

Henry Ruyfch, the son of the preceding, who died in 1727, published a "Theatrum universale omnium Animalium, &c. 240 Tabulis ornatum," 1718, in two vols. folio. He is said to have been the sole depositary of the secret of his father, by which those beautiful preparations were made, which retained the appearance of life; and Ruyfch was reproached for allowing the contrivance to perish with his family. But the modern improvements in the art of injection do not probably fall short of his expedients, in the demonstration of the vascular structure of the different organs of the body. See Eloy Dict. Hist. de la Med.; Eloge de Fenelon; Hutchinso, Biographia Medica.

RUYSCHIA, in *Botany*, received that appellation from Jacquin, in memory of professor Frederick Ruyfch, the celebrated anatomist; another plant, which had borne his name, being referred to *Dracocephalum*. He is noticed by Haller, Bibl. Bot. v. 2. 98, for having directed his anatomical skill to the maceration and dissection of leaves, as well as for his fondness for exotic plants. He appears as the editor, commentator, and translator into Latin, of Commelin's valuable *Hortus Amstelodanensis*.—Jacq. Amer. 75. Schreb. Gen. 144. 823. Willd. Sp. Pl. v. 1. 1116. Mart. Mill. Dict. v. 4. Swartz Ind. Occ. 501. t. 11. Juss. 428. Lamarck Illustr. t. 135. (Souroubea; Aubl. Guian. 244. t. 97. Juss. 428.)—Class and order, *Pentandria Monogynia*. Nat. Ord. uncertain. Juss.

Gen. Ch. *Cal.* Perianth inferior, double; the outermost longest, in three deep unequal segments, coloured; the inner of five roundish, concave, obtuse, converging, permanent leaflets. *Cor.* Petals five, ovate, flattish, obtuse, reflexed, thrice as long as the inner calyx. *Stam.* Filaments five, awl-shaped, flat, spreading, shorter than the petals; anthers oblong, incumbent. *Pist.* Germen superior, roundish-ovate; style none; stigma quadrangular, cruciform, flat. *Peric.* Berry of two cells. *Seeds* numerous.

Ess. Ch. Calyx double; the outer in three deep unequal

segments; inner of five leaves. Petals five, reflexed. Style none. Berry of two cells, with many seeds.

Obf. Aublet describes the stigma as of five angles or points, and the germen of five cells.

1. *R. chrysifolia*. Purple Ruyfchia. Jacq. Amer. 75. t. 51. f. 2. Willd. n. 1. Swartz Ind. Occ. 502.—Leaves obovate, obtuse, without transverse veins. Two segments of the outer calyx shorter than the inner one.—Native of the vast boggy forests in the interior parts of Martinico, where Jacquin found it flowering in April. Nobody else seems to have gathered this species. The *stem* is rather shrubby, two feet high, growing parasitically upon trees. *Leaves* alternate, on short stalks, obovate, obtuse, entire, coriaceous, shining, smooth, four inches long, with a solitary mid-rib, and no lateral veins. *Clusters* terminal, quite simple, solitary, erect, many-flowered; cylindrical, nine inches long; the common stalk cylindrical, thick and smooth; partial ones scattered, simple, short, spreading. *Flowers* between the size of a laurullinus and hawthorn blossom, inodorous, with purple petals. *Filaments* also purple, usually five, often seven, sometimes six. Jacquin did not see the ripe *fruit*, but conjectured it to be a berry.

2. *R. Souroubea*. Red and yellow Ruyfchia. Swartz Ind. Occ. 504. Willd. n. 2. (*Souroubea guianensis*; Aubl. Guian. 244. t. 97.)—Leaves obovate, emarginate, with a small point, and many transverse veins. All the segments of the outer calyx longer than the inner one.—Gathered by Aublet, on the banks of the river *du Gallion*, in Guiana, flowering in October. The *stems* are shrubby, but brittle, long and trailing, supporting themselves on the neighbouring bushes, but drooping at the ends; their outer bark ash-coloured, easily peeling off. *Leaves* alternate, on short thick stalks, smooth, fleshy, four inches long, marked with numerous, transverse, not very evident, veins. *Clusters* terminal, solitary, long and drooping, of numerous *flowers*, much larger than those of the first species; their partial stalks an inch long. The *outer calyx*, as we choose to call it, rather than a *bractea*, consists of three divisions, each near an inch long, of a coral red, one of whose segments is a tube, closed at the end, the other two obovate, or spatulate, concave above. *Inner calyx* of five or six yellowish leaves, firm, folding over each other. *Corolla* of a golden yellow, described by Aublet as monopetalous; but Swartz, who examined this author's specimens, says otherwise. *Stamens* yellow. Ripe *fruit* not seen by Aublet. No other person appears to have gathered this plant. The habit of the genus, and in some measure the peculiar conformation of the *outer calyx*, resemble *MARGRAVIA*; see that genus, and *ASCIMUM*.

RUYSCHIANA. See *TUNICA* and *EYE*.

RUYSDAEL, JACOB, in *Biography*, was born at Haerlem in 1636, and at first studied surgery as his profession, although he had given early proofs of a fine taste in the art of painting; to which, at length, his attention was entirely directed by Nicholas Berghern, with whom he lived in habits of intimacy. He is said by some writers to have improved his taste in Italy, but scarcely a particle of Italian taste is to be found in his works. Nature was the school in which he studied; her pure ethereal tints, her peculiar forms, the freshness of the morning, the brilliancy of mid-day, and the spirit-stirring tone of twilight, were the foundation of the principles by which he was governed, and in the contemplation of which he laid the basis of that perfection of locality to which he successfully aspired.

His landscapes are generally scenery in the neighbourhood of his residence, or occasionally taken from the rocky borders

carrying on at Breda, which De Witte had protracted, while he hastened the naval preparations. The Dutch fleet appeared in the Thames under the command of De Ruyter, which threw the English into the utmost consternation. A chain was thrown across the Medway, and some new fortifications were added to Sheerness and Upnore castle: but these preparations were unequal to the urgency of the case. Sheerness was soon taken, though defended with the utmost valour by sir Edward Sprague. Having the advantage of a spring tide and an easterly wind, the Dutch, with six men of war and five fire-ships, pressed on and broke through the chain, and burnt several English men of war in their course: among these was the Royal Oak, the commander of which, captain Douglas, perished in the flames, though he might readily have escaped. "Never was it known," said he, "that a Douglas left his post without orders." The peace which soon after followed gave some repose to De Ruyter, till the alliance between Charles II. and Lewis XIV. for the ruin of the Dutch republic, again called him to the defence of his country. With a fleet of 91 sail, in June 1672, De Ruyter attacked the combined fleets of 130 sail, commanded by the duke of York, lord Sandwich, and count d'Estrées, in Solebay; and after an engagement, which he represented as the most obstinate that he ever witnessed, night parted the adversaries, each claiming the victory. Lord Sandwich and count d'Estrées lost their lives, and the other losses were nearly equal, but De Ruyter kept the sea, and safely convoyed home a large fleet of merchantmen. The French kept aloof, and suffered very little.

De Ruyter was now doomed to suffer danger from a different cause. During the popular fury against the opposers of the house of Orange, which proved fatal to the De Wittes, De Ruyter, as one of the party, notwithstanding the great services which he had rendered his country, was attacked in the streets of Amsterdam with all sorts of weapons, but escaped without much injury. When William was raised to the stadtholdership, the services of this great admiral were too important to be slighted through party disputes, and in 1673 he was sent to sea with a strong fleet in quest of the combined English and French, who were on the Dutch coast, under the command of prince Rupert. An indecisive engagement ensued on the 7th of June, in which De Ruyter disengaged Tromp from the French squadron which had surrounded him. The battle was partially renewed on the 14th, and in August, as we have seen in the article RUTERT, a more severe engagement took place, in which an English and two Dutch admirals were killed, and both parties claimed the victory. De Ruyter, however, received the thanks of the stadtholder for his good conduct on this occasion. Peace between England and the Dutch soon after followed, and never since have the two nations contested the empire of the ocean with such mighty force, and so determined a spirit. France, at this time, was rising fast to be a maritime power, and Holland, in alliance with Spain, had to contend with her for the superiority. De Ruyter, in 1674, made a fruitless expedition to the French Caribbee islands. In the beginning of 1676 he was sent with a fleet to Sicily, which had been encouraged by the French to revolt from the Spaniards. He fell in with the French fleet under the duke de Vironne, and an action ensued, which lasted the whole day, with no decisive advantage to either side. De Ruyter repaired to Leghorn to refit, and then, forming a junction with the Spanish fleet, they proceeded towards Messina. The French came out to meet them, led on by the celebrated Du Quesne, and a second battle took place on the 21st of April. The Spaniards kept at a cautious distance, but De Ruyter, like himself,

rushed to the centre, broke the French line, and was in the act of chasing, when a cannon-shot wounded him in the left heel and right leg. A fever supervened, which within a week put an end to his life in the port of Syracuse, at the age of 69, deeply regretted by his country and admired by all Europe. The king of Spain had, only a few days previously to this, conferred upon him the title of duke, with a pension. His remains were magnificently interred at Amsterdam at the public expence, and a superb monument was erected to his memory. Univer. Hist. Hume. Campbell's Lives of the Admirals, edit. 1813.

RUZA, in *Geography*, a town of Russia, in the government of Moscow; 48 miles W.N.W. of Moscow. N. lat. 55° 46'. E. long. 36° 2'.

RUZASUS, ZAFFONE, in *Ancient Geography*, a port in the eastern part of Mauritania Cæsariensis, situated E. of Ruscurium.

RY, in *Geography*, a town of France, in the department of the Lower Seine; nine miles E. of Rouen.

RYACOTTA, a town of Hindoostan, in Mysore, strong, and well furnished with guns, ammunition, and provision for its defence, but taken by the British in July 1791; 75 miles S. of Seringapatam. N. lat. 12° 26'. E. long. 78° 5'.

RYADER. See RIADER.

RYAL. See RIAL.

RYAL, a name given to the noble, which, on account of the scarcity of gold in the time of Henry V. of England, was diminished in size, whilst it retained its former value, but was restored by Henry VI. to its original size, and caused to pass for 10s. under this appellation. (See *Rose-noble*.) This ryal of 10s., and also the angel of 6s. 8d., with their divisions of half and quarter, were the sole gold coins, till, in 1485, Henry VII. published the double ryal, or sovereign of 20s. accompanied by the double sovereign of 40s. James I. of England issued rose-ryals of 30s., and spur-ryals of 15s.; angels of 10s., and angelets of 5s.; till his ninth year, when gold was raised in the proportion of 1s. in 10s.

RYALCHERY, in *Geography*, a town of Hindoostan, in the Carnatic; 10 miles N.W. of Bomrauzepollam.

RYAN, LOCH, an arm of the sea, which extends itself in a S.E. direction into Wigtonshire, Scotland, forming, with the bay of Glenluce, the peninsula denominated the Ruins of Galloway. It is about ten miles in length from its entrance to Stanraer, which is situated at its head, and varies in breadth from two to four miles. On its eastern side stands the little village of Cairn, contiguous to which is a very safe and commodious bay, with good anchoring ground, and depth of water sufficient for ships of any burthen. King William's fleet anchored here on their passage to Ireland. Opposite to this village a sand-bank runs a considerable way across the loch, but few accidents ever happen upon it, and it even contributes to the safety of the southern part of the bay, by breaking the force of the tides, which flow strongly in the direction in which it lies. This bank abounds with oysters of a most excellent quality. Besides Cairn bay, there are several other excellent anchoring bays in the loch, called Portmore bay, the Wig bay, the bay of Soleburn, and the bay of Dalmennock. In short, the anchoring is good and safe in almost every part of the loch. For some further remarks relative to this arm of the sea, see STANRAER. Sinclair's Statistical Account of Scotland, vol. i. 8vo. Edin. 1791. Carlisle's Topographical Dictionary of Scotland, 4to. 1813.

RYANIA, in *Botany*, was named by Vahl in just commemoration of John Ryan, M.D. F.R.S., a very active and

and intelligent correspondent, to whom he was indebted for many specimens of rare plants from the islands of Santa Cruz, Montserrat, &c.—Vahl. *Eclog. fasc. i. 51.* Willd. *Sp. Pl. v. 2. 1164.* Mart. *Mill. Dict. v. 4.*—Clafs and order, *Polyandria Monogynia.* Nat. Ord. *Tiliaceæ*, Juff.

Gen. Ch. *Cal.* Perianth inferior, of five lanceolate, tapering, spreading, finely ribbed, coloured, permanent leaves. *Cor.* Petals none. Nectary between the germen and stamens, the height of the former, pitcher-shaped, very villous. *Stam.* Filaments numerous, about 60, in a double row, awl-shaped, a little shorter than the calyx, smooth, except a few hairs at the base; anthers erect, awl-shaped, one-third the length of the filaments, pointed, corrugated, naked, finally waved at the edge. *Pist.* Germen superior, ovate, very villous; style smooth, the length of the stamens; stigmas four, convex. *Peric.* Berry dry, corky, nearly globular, of one cell, with five longitudinal tuberculated receptacles, from its inner coat. *Seeds* numerous, ovate, nearly globular, brown, besprinkled with a few minute hairs, and each half enclosed in a membranous tunic, with three double wings.

Eff. Ch. Calyx inferior, of five coloured permanent leaves. Petals none. Nectary pitcher-shaped, between the stamens and pistil. Berry corky, of one cell, with many tunicated seeds.

1. *R. speciosa.* Vahl. *Eclog. t. 9.*—Found by Dr. Ryan, in the island of Trinidad. A tree, with ash-coloured round branches, finely downy towards the ends. *Leaves* alternate, stalked, elliptic-oblong, pointed, entire, smooth on both sides, except a mealiness on the mid-rib beneath. *Stipulas* awl-shaped, hoary, rather longer than the footstalk, deciduous. *Flowers* axillary, mostly solitary, on short simple stalks. *Leaves* of the calyx an inch and half long. *Berry* double the size of a walnut. *Seeds* rather bigger than those of Coriander. Vahl conceived this genus to be allied to *Lactia*, but distinct in the nectary, permanent calyx, four stigmas, awl-shaped (not round) anthers, and other particulars.

RYCKE, THEODORE DE, in *Biography*, a learned critic, born at Arnheim in 1640; was first an advocate at the Hague, and then professor of history at the university of Leyden. In 1681 he delivered an oration "De Gigantibus," which, with a dissertation "De Primis Italiae Colonis et Aeneæ adventu," he added to an edition of Stephanus Byzantinus and Scymnus Chius, Lugd. Bat. 1684. He also published a valuable edition of Tacitus, with notes and illustrations, in 1687, in two vols. 12mo. He died in 1690.

RYCQUIUS, JUSTUS, was born at Ghent in 1587, and educated at Douay. From this place he travelled into Italy, and was for some time librarian to count Lodovico Salero. Returning to the Low Countries, he was made canon of Ghent, and resided some time at Louvain. In 1624 he was appointed by Urban VIII. to the chair of eloquence in the university of Bologna, where he died in 1627. He published a number of Latin poems, and other works, but is chiefly known by his treatise "De Capitolio Romano," 1617, containing a description of the works of art, ancient and modern, preserved in that relic of antiquity. This performance obtained for him the title of a Roman citizen. It was reprinted at Leyden by Gronovius in 1696, with notes and plates. Gen. Biog.

RYD, in *Geography*, a town of Sweden, in the province of Upland; 20 miles S. of Upsal.—Also, a town of Sweden, in the province of Smaland; 22 miles E.S.E. of Jonkiöping.

RYDAHOLM, a town of Sweden, in the province of Smaland; 22 miles W.N.W. of Wexio.

RYDAL HEAD, a mountain of England, in Westmoreland; two miles N. of Ambleside.

RYDAL WATER, a lake of England, in Westmoreland, which communicates with the Windermere lake.

RYDALL, a river of Wales, which runs into the sea at Aberystwith.

RYDDA, in *Ancient Geography*, a city which the Jews conquered from the Arabians, under Alexander Jannæus. Joseph. *Antiq. lib. xiv. cap. 2.*

RYDER, Sir DUDLEY, in *Biography*, was born in the year 1691, and having received a good elementary education, he was brought up to the profession of the law. It may be observed, that the family from which the subject of this article was descended, had been very long established in Yorkshire, and took their name from Ryther, in the hundred of Barkston, in that county, hence the name has been written differently at different periods, as Rythre, Ryther, or Ryder. It appears from Dugdale's Baronage, that William de Ryther was summoned to parliament among the barons of the realm, from the 21st of Edward I. till the 1st of Edward II., and that he was succeeded by John de Rythre, governor of Shipton castle. Sir Dudley Ryder was appointed solicitor-general to his majesty George II. in 1733; in 1736 he was advanced to the office of attorney-general, and in 1754 he was appointed to the high office of lord chief justice of the court of king's bench. In the year 1756 his majesty, as a reward for his long and very faithful services, determined to advance him to the dignity of the peerage, by the title of lord Ryder, baron of Harrowby in Leicestershire, and a warrant was accordingly signed by the king for that purpose, on the 24th of May; but sir Dudley died on the following day, before the patent could be completed. He left a son, Nathaniel, the first lord who was so created in 1776. He died in 1803, and was succeeded by his eldest son, Dudley, the present lord.

RYDER, or *Ruyder*, in *Commerce*, a gold coin in Holland. The new stand-pennings, or ryders, are fixed by the regulation of 1749 at 14 florins, and the half ditto at 7 florins. The alloy and value, &c. are as follow:

	Assay.	Weight.	Contents in pure Gold.	Value in Sterling.
	car. gr.	oz. dwt. gr.	grains.	<i>L. s. d.</i>
Double ryder	standard.	o 12 21	284.2	2 10 3½
Ryder -	ditto.	o 6 9	140.2	1 4 10
Half ryder -	ditto.	o 3 4½	70.1	o 12 5
Ducat -	B. 1 2¼	o 2 5¾	52.8	o 9 4

*Impressions.*—The ryder has on the front, an armed horseman, with a drawn sword; the legend expresses the province in which it has been coined, thus: MO. AUR. PRO. CONF. BELG. ZELAND, that is, *Moneta auræ provincie confederationis Belgicæ Zelandiæ* (gold coin of Zeland, a province of the Belgic confederacy), with the arms of the province at bottom: reverse, the arms of the United Provinces, with 14 Gl. (14 guilders or florins); legend, CONCORDIA RES PARVÆ CRESCUNT (small things increase by concord). The half ryder bears the same impressions, except that it is marked 7 Gl.

The ducat has a foot soldier with a drawn sword, and a bundle of arrows in his left hand; legend, CONCOR. RES PAR. CRES., that is, *Concordia res parvæ crescunt*, as above, and the letters, HOL. or ZEL. &c. to distinguish the province: reverse,

reverse, a square, with ornaments and the following words in five lines, MO. ORD. PROVIN. FÆDER. BELG. AD LEG. IMP.; that is, *Moneta ordinaria provinciarum federatarum Belgicarum ad legem Imperii*, (the common coin of the confederated Belgic provinces, according to the law of the empire).

RYDER, or *Rider*, to a bill. See PARLIAMENT.

RYDRAIRE, in *Geography*, a town of Hindooftan, in Baramaul; 28 miles N. of Namaicul.

RYDROOG, a town and fortrefs of Hindooftan, in Myfore; 128 miles N. of Seringapatam. N. lat. 14° 40'. E. long. 76° 52'.

RYE, in *Botany*. See SECALE.

RYE, in *Agriculture*, a species of corn much cultivated in some of the northern districts. It is a sort of crop that approaches the nearest to that of wheat of any that is at present in cultivation. There are two varieties of this grain, the *winter* and *spring* rye, or what is often distinguished into the *black* and *white*, or Dantzic sort, but the former is the largest and the most plump and hardy, consequently the most frequently grown by the farmer, however the spring kind may often be employed with success and advantage. This kind of grain is so capable of sustaining the effects of the weather, that when sown in the autumn it is seldom injured by the most severe winters; it is likewise more early in the spring than wheat, and though not equally valuable, is more certain of producing a good crop in general than that grain is.

*Soil*.—This is a sort of crop which is capable of being grown on most kinds of land, but the light dry sandy soils that cannot be converted to the purpose of wheat or barley, are probably the only ones on which it can be cultivated to advantage, from being the most adapted to it, and from few of them being so light or poor as not to afford good crops. It can, of course, only be introduced with success on such lands as are incapable of producing other sorts of corn to advantage. And from fowls being less fond of it than most other sorts of grain, it may be the most proper to be cultivated on those portions of ground that are situated close around the farm-houses and yards.

It is a crop which is mostly grown after early fed turnips, clover, peas, and other similar products, as well as after naked fallows. In particular cases, when grown on the cold and heavy kinds of soil, the grain is found to be much later in becoming ripe than on such as are dry and light in their quality.

This is also a kind of crop which, as in that of wheat, requires the land to be brought into a tolerable state of mellowness, and to be perfectly cleared from weeds. In many districts where intended to stand for a crop, it is the custom to put it in upon some sort of fallow, but where it is only to be fed off by sheep, seldom more than one ploughing is given, the land being broken up and fallowed for turnips, immediately after the green rye has been sufficiently eaten down by sheep or other animals. And it is the practice in some places to apply manure immediately for this crop; but where the soil is in a suitable state of tillage, and has not previously been too much exhausted by the growth of grain crops, it may be more proper, especially where it is not to be fed off, to defer the application of the manure, in order that it may be employed for the turnip or other green crop that is to succeed, the use of manure being apt to bring up weeds, and render it difficult to be kept clean.

*Seed and Sowing*.—In respect to the time of sowing this sort of grain, it is, in general, pretty much the same as that for wheat where a crop is intended, but when cultivated for green food for animals, it may be advantageous to

sow it more early, as in August and September, but it may be sown in October, and during the winter months, until the beginning of March, in particular cases, as where the early sowings have failed, or there is an intention of having a succession of this feed for sheep. In which cases, according to Mr. Bannister, it is usually sown on one ploughing on a wheat or other stubble where the field is to come in course for turnips in the following year. And the above writer says that the general allowance of feed, where the crop is designed to remain for grain, is, in most situations, from about two bushels to two and a half; but when the intention is to feed it off, three, or even more, may be a better proportion, as the plants, in such cases, should stand considerably thicker upon the ground, in order that the largest possible quantity of green food may be provided for the animals. And as the vegetation of this sort of crop is rather slow, it may be proper to put it into the ground when it is in a tolerably dry condition, otherwise much of it may perish, especially in wet seasons, and where the land is rather heavy.

It is likewise stated in the Report of Yorkshire, that it was formerly a prevailing custom to blend several other sorts of seeds with that of rye, and the practice still continues in some districts, in respect to wheat and winter tares, but it is by no means either advisable or useful, in Mr. Donaldson's opinion, since, in the first case, the rye is in a state fit for reaping long before the wheat, consequently much loss must be sustained by the farmer, and in the latter it is mostly in a state to be cut as green food, some weeks before the tares, and becomes ripe at much too early a period for them.

And in cases where wheat is blended with rye, it is often termed *meslin*, the proportion of the latter to that of the former being regulated by the nature of the soil, and the opinion of the grower, the general principle being that of giving the largest proportion of rye to the lightest kinds of ground.

*After-culture*.—In cases where this crop is grown for the purpose of the grain, it will be necessary to keep it as clean as possible in the early stages of its growth by horse and hand weeding, and hoeings according as it is sown, when they may appear requisite; but where the intention is merely that of affording a supply of green food, for the use of sheep or other animals in the more early spring months, no further culture will be wanted after the crop has been put into the ground. This sort of crop is known to be ready to cut by the straw of the stems becoming of a yellowish colour, the ears hanging down in a bending manner, and the grain feeling hard and in a plump and full condition.

On the poor sandy soils of Suffolk good crops of this sort are seldom produced, and on those of a better quality the produce is rarely more than from two to three quarters on the acre. But in the north riding of Yorkshire it is stated, by the author of the Agricultural Report of that district, to amount to from three to six quarters to the acre of land.

In cases where this sort of grain is free from weeds, and cut when the weather is fine, it may be secured in the stack as fast as the reaping proceeds, without its being endangered by it. And the straw of this sort of grain is found to be superior to that of wheat, for the purpose of thatch, as well as for the use of the collar-makers, who require much of it.

The practice of farmers is sometimes, where rye is intended to stand for a crop, to feed it with sheep in the early spring, as in the beginning of March; but this should never be done

except where the crop is very luxuriant, and at so early a period as that there may be no danger of destroying the new formed ear of the grain. This kind of crop is also cultivated in particular cases, as where the ground is sufficiently light and dry to be turned down as a manure: where this is the case, the crop should always be turned in while in its most green and succulent state, and when the weather is moderately dry, in order that it may be more quickly reduced by putrefaction into a manure. And, in the more southern districts, it is not unfrequently grown for the purposes of the tanners, who have recourse to it in the preparation of leather.

*Application.*—The most usual application of this crop is as a green food for sheep in the early spring, before the turnip crops are ready. When grown in this view it is necessary, the author of Practical Agriculture says, to have attention to different circumstances, in order to derive the utmost advantage from the crops. As this grain begins to shoot out, or spindle, as it is termed by farmers, much earlier than wheat, care should be taken that the feeding of it down is begun at a sufficiently early period before the ear is formed in the *hose*, as the latter end of February or beginning of March, otherwise the stem or blade becomes firm and sticky, and the succession of green feed after the first eating extremely small. Indeed this may be done earlier than the first of these periods, in cases where the season is mild and open, and persevered in till the end of April. In all cases it is, however, advisable to let the crop be so advanced in its growth as to cover the ground tolerably before the sheep are turned in. As this sort of green food is said to have much effect in promoting the flow of milk in such ewes as have lambs, probably from its succulency, and its stimulant properties being applied immediately after the severity of the winter season, when the bodies of animals are known to be more capable of being excited by the action of stimuli, and when there is scarcely any other sort of green feed that can lessen its operation by being taken along with it, the culture of it must be the most advantageous, it is supposed, where sheep husbandry is extensively combined with that of tillage, especially that department of it which relates to the feeding of lambs. As by this means, from the quantity of succulent nutritious food that is provided, the lambs are prevented from being stinted in their growth while young, which is a matter of the utmost importance in their future feeding. And that in thus feeding the crop off by sheep it will constantly be necessary to keep the fields properly divided by means of hurdles, as in this way the loss of food will be much less, and some parts will become fresh while the others are eating down, which are advantages not to be disregarded in cases of this kind.

But Mr. Bannister thinks, that, notwithstanding what has been urged in favour of a rye pasture, it is scarcely worth the while of any farmer to attempt the cultivation of this grain, who does not keep large numbers of ewes and lambs; for as the seed usually fetches a high price, every advantage attending the crop will be more than balanced by the superior charges in the cultivation, except in the instance above-mentioned, where no expence should be spared to maintain the lambs in a thriving way, and to prevent their growing hard and sticky, as the butchers term it; for if lambs once sink in flesh, it is beyond the art of man to restore them to their former thriving state again.

Rye is, in many parts of the country, used for bread, either alone, or mixed with wheat.

Rye is also a grain which is much used in the distilleries, where it can be procured in large quantity, and also by the ginger-bread bakers. In the Rural Economy of Yorkshire it is observed, that before the use of lime was prevalent,

much rye was grown on the lighter lands upon the margin of the vale, and in the moor-lands scarcely any other crops than rye and oats were attempted. Now rye is principally confined to the moorland dales; and even there the alteration of soils by lime has been such, that wheat is become the more prevalent crop. Nevertheless, on light sandy moorland soils, rye is generally more profitable than wheat; and the bread which is made from a mixture of the two grains is here esteemed more wholesome to persons in general, than that which is made from wheat alone.

It is cultivated in many districts as a good spring green feed for sheep, particularly ewes and lambs. This is greatly the case on the South Downs, in the county of Surrey. It is there sown in the late summer months, or the very beginning of those of the autumn, the more early the better. When other food is scarce in the spring and in the lambing season, the ewes and lambs are turned upon it, proper portions being hurdled off for the purpose.

Some suppose it prepares well for turnips, and that on many accounts it may be raised with much use and advantage on open exposed sandy soils, where wheat crops will not succeed, for being fed off, and insure far better crops of the above roots, than are commonly met with in such soils and situations. There would, in these cases, it is said, be the benefit of an increased quantity of food, and of course an increase in the number of live-stock, which would produce a greater abundance of manure, and, consequently, of grain crops ultimately. The trouble and expence of adopting such a method of practice would be but trifling, inasmuch as the ground would be broken up only in the autumn instead of the spring; in return for which sheep-feed would be procured, and, at the same time, the land be well dressed for the further crop, which should constantly have a full supply of manure when the feed is put into the land.

This crop, on the whole, deserves more attention than it has commonly met with, as it forms one of the links in the chain of green food, by which live-stock, on arable farms, can be fed and supported the whole year round.

In many parts of France there have been certain years in which this grain, from no apparent cause, has proved noxious, and sometimes even poisonous. M. Perrault travelling through Sologne, was informed that the rye of that province was sometimes so corrupted, that those who eat of the bread that had much of the corrupted grain in it, were seized with gangrenes in different parts of the body, which were not preceded by any fever, inflammation, or any considerable pain; and that the gangrened parts usually fell off after a time of themselves, without the assistance of chyrurgical instruments. The grains of rye thus degenerated, are black on the outside, and tolerably white within; and when they are dry, they are harder and closer than the natural good grain; they have no ill taste, but sometimes they have a viscid metallic-like honey hanging to one end of them. They grow longer than the other grains in the same ear, and are found from one or two to seven or eight in the same ear. Some have supposed that these were not the proper feeds of the plant, but some other extraneous bodies that got in among them; but it is evident, from a close inspection, that they are really the genuine feeds, only altered by some accident; the coats, and the furrow, and even the germen for the young plant, being entirely the same as in the natural feeds.

The places where the rye is found to degenerate in this manner, are all a dry and sandy soil. In these places there is scarcely any soil in which more or less of these large feeds are not found among the others, but where there are but few of them, the ill effects are not perceived. The seasons when the degeneracy is greatest, and the effects the worst

of all, are, when there have been excessive rains in the spring, and there come on excessive heats in the succeeding summer.

The bread which is made of the rye that holds ever so much of this bad corn, is not distinguishable from other rye-bread by the taste, and seldom produces its ill effect, till some considerable time after it is taken. Beside the gangrenes already mentioned, it not unfrequently brings on other bad consequences, such as drying up the milk of women who give suck, and occasioning sometimes malignant fevers, accompanied with drowfiness, ravings, and other dangerous symptoms. The part usually seized by the gangrene is the legs, and this often in a very frightful manner. The arms are the next part most subject; but all the other parts of the body are subject to it.

The first symptom of this approaching gangrene is a stupefaction and deadness in the part; after this there comes on some pain, though not violent, and the skin becomes livid; sometimes the skin shews no mark of it, but the pain and swelling increase; and it is necessary to make an incision into the flesh, to find the gangrened part. In the more desperate cases, the only remedy is, the taking off the part; and if this is neglected, the flesh is all wasted, and the skin becomes black, and clings round the bones, and the gangrene appears again in the shoulders.

The poorer people are only subject to this disease; and, as they principally eat the rye-bread, and as those years when there is most of this bad grain among the ears of rye, produce most of these disorders, it has been judged certain that the rye is the occasion of it. It may deserve enquiry, however, whether that grain may not be innocent of the mischief, and its degeneracy and the distemperature attributed to it may not both be the effect of the same bad constitution of the air. If it proves, on enquiry, that only those who eat of the rye are subject to the disease, it will seem a proof of its being really owing to it; and in this case the mischief may be prevented by the sifting the grain before it is ground, the degenerated grains being so long that they will all remain in the sieve that lets the others through. The experiment has been made on the spot, by giving the flour of the corrupted grains alone to animals, and it is said they have been killed by it. *Philos. Trans.* N<sup>o</sup> 130.

*RYE-Grass*, the common name of a particular sort of grass. See *RAY-Grass*.

It has been observed, from the trials made at Wooburn, under the care of Mr. G. Sinclair, that sheep eat this grass, when it is in the early stage of its growth, in preference to most others; but after the seed approaches towards perfection, they leave it for almost any other kind. A field in the park at the above place was laid down in two equal parts, one part with rye-grass and white clover, and the other part with cock's-foot and red clover: from the spring till midsummer the sheep kept almost constantly on the rye-grass; but after that time they left it, and adhered with equal constancy to the cock's-foot during the remainder of the season.

*RYE*, or *West Rye*, in *Geography*, a borough, market-town, and cinque-port, under the title of "ancient port and town," in the hundred of Gostrow, rape of Hastings, and county of Suffex, England, is situated on the coast of the British Channel, at the distance of 76 miles E. by W. from Chichester, and 62 miles S.E. by E. from London. It is of very high antiquity, but its early history is little known. It seems clear, however, that it was one of the original cinque-ports, and is mentioned as a member of them generally, in a charter granted by king Henry III. In the

reign of Edward III. the whole town was environed with a strong wall, and guarded by towers, under the superintendance of William d'Ypres, earl of Kent. At that period Rye was so considerable a port, that it furnished no fewer than nine armed vessels to the royal fleet, when the king undertook the invasion of France; but it suffered materially in the next reign, having been plundered and burnt by the French, who took advantage of the then distracted state of the country, to attack such of the coast-towns as were least capable of resistance. It soon, however, recovered from this disaster, and became a port of considerable consequence; but the rise of others on the same coast has rendered it for the last century comparatively unimportant. The harbour, which lies to the south-east of the town, is at present in a neglected state, notwithstanding it admits vessels of a large size to come quite up to the town-quay, about a mile and a half from its entrance. At spring tides the sea rises so high, and spreads itself so much, that two-thirds of the town are surrounded by water. The mackarel and herrings caught here in their seasons are reckoned the finest of the kind brought to the London market.

Rye is a borough of itself by prescription, as well as by charters granted in confirmation of its privileges. The corporation consists of a mayor, bailiff, jurats, and freemen. The mayor and bailiff are chosen from among the jurats on the Monday after St. Bartholomew's day, by the votes of a majority of freemen. When a vacancy occurs among the jurats, the mayor nominates a freeman to supply it, but he must be approved of by the jurats before his appointment becomes valid. Rye sends two members to parliament, who are ostensibly elected by the mayor, jurats, and freemen inhabiting the borough, and paying scot and lot; but, in fact, they are returned through the influence of the treasury, which is paramount in all the cinque-ports. The principal articles of trade here are, hops, wool, timber, kettles, cannon, chimney-backs, and other iron goods, from the works at Bakeley and at Breed. There are two weekly markets, on Wednesday and Saturday; and two annual fairs, on Whitmonday and the 10th of August.

The town of Rye occupies a considerable eminence, and is, generally speaking, regular and well built. In the centre of the principal street stands the market-house, the higher story of which is appropriated as a town-hall, for the use of the corporation. The church is constructed of stone, and is one of the largest parochial edifices of the kind in England, but does not otherwise claim particular attention. Here is besides a chapel, which was lately appropriated to the French refugees, who settled in the town and its vicinity during the late war; also meeting-houses for Methodists, Quakers, and other Dissenters. Here are likewise two free-schools, one of which was erected and endowed by a Mr. Peacock in the year 1644; and the other by a Mr. Saunders, at a later period. The only monastic establishment in Rye was a priory of Augustine friars, which existed previous to the time of Edward III. and continued to flourish till the general dissolution of religious houses by king Henry VIII. The church formerly belonging to this monastery is still standing, having been converted into a store-house for mercantile goods. Some remains of the ancient walls of the town may yet be traced, but the ditches are entirely filled up.

According to the parliamentary returns of 1811, this town and out-liberty contain 476 houses, and 2681 inhabitants. Camden's *Britannia*, by Gough, Suffex, folio, 1789. *Beauties of England and Wales*. vol. xiv. 8vo.

*RYE*, a town of Denmark, in North Jutland, formerly important, but now much reduced. The church at Rye,

in popish times, was reckoned to be a very sacred place; 16 miles W. of Aarhuys.

RYE, a township of New Hampshire, in America, on the sea-coast of Rockingham county, opposite the isle of Shoals, and 8 miles S. of Portsmouth: incorporated in 1719, and containing 1020 inhabitants.—Also, a township of New York, in West Chester county, in Long Island found; 36 miles N.E. of New York city.—Also, a township in Cumberland county, Pennsylvania, containing 1356 inhabitants.—Also, a township in Cumberland.

RYECHUNGA, a town of Bengal; 13 miles N.W. of Beyhar.

RYEGATE. See REYGATE.

RYEGATE, the fourth-easternmost township of Caledonia county, in the state of Vermont, separated from Bath in New Hampshire by Connecticut river; containing 812 inhabitants.

RYELAND SHEEP, a breed of fine-woolled sheep, originally met with in the greatest perfection in a district of Herefordshire, termed the Ryelands. See SHEEP.

RYER, ANDREW DU SIEUR DE MALEZAIS, in *Biography*, was born at Marcigni, in Burgundy. Little is known of his history, but he became gentleman in ordinary of the king's bed-chamber, and knight of the Holy Sepulchre. He resided a considerable time at Constantinople in the king's service, and was consul for the French nation in Egypt, from which opportunities he derived a knowledge of the Arabic, Turkish, and other Oriental languages. He died in France, about the middle of the 17th century. His chief works as a literary man are, "A Turkish Grammar;" "A French Translation of the Koran," and another of the "Gulistan" of Saadi. His version of the Koran is in no great estimation, as he is said to have mixed the reveries of Mohammedan commentators with the original text.

RYER, PETER DU, a dramatic and miscellaneous writer, was born of a good family at Paris, in 1605. He procured a place of secretary to the king in 1626, which his poverty obliged him to sell, and he afterwards served in the same capacity Cæsar, duke of Vendome. In order to support his family he employed his pen in prose and verse. He composed nineteen pieces for the theatre, which were successful at the time of their appearance. Two or three of his tragedies obtained the applause of maturer criticism. His "Alcyonée" so much delighted queen Christina, that she had it read to her three times in one day. His "Scævole" still keeps its place on the stage. Du Ryer was admitted into the French Academy in 1646. A short time before his death he obtained the office of historiographer royal, with a pension. He died in 1658.

RYES, in *Geography*, a town of France, in the department of the Calvados, and chief place of a canton, in the district of Bayeux. The place contains 650, and the canton 10,510 inhabitants, on a territory of 147½ kilometres, in 29 communes.

RYEWATER, a river of the county of Kildare, Ireland, which passing by Carton, falls into the Liffey, near Leixlip.

RYKOWICZA, a town of Lithuania, in the palatinate of Brzesc; 25 miles S.E. of Brzesc.

RYKSDALER, in *Commerce*. See RINDOLLAR.

RYKSORT, a Danish silver coin, reckoned at twenty-four shillings. See RINDOLLAR.

RYMABAD, in *Geography*, a town of Hindoostan, in Myfore; 15 miles E.S.E. of Chinna Ballabarum.

RYMAROW. See ROMERSTADT.

RYME. See RIVME.

RYMENAUT, in *Geography*, a town of France, in the

department of the Two Nethes, situated on the Dyle; five miles E. of Malines.

RYMER, THOMAS, in *Biography*, a critic and antiquary, was born in the north of England, and educated at the grammar-school of Northallerton. He was admitted a scholar at Cambridge, then became a member of Gray's Inn, and at length was appointed historiographer to king William, in place of Mr. Shadwell. He wrote "A View of the Tragedies of the last Age," and afterwards published a tragedy named "Edgar." For the office of a critic he was certainly not well qualified, for he wanted candour; nor is his judgment much to be relied on, as he could condemn Shakspeare with such rigid severity. His tragedy will shew, that his talents for poetry were by no means equal to those whose poems he has publicly censured. But though he has no title to the appellation of poet or critic, as an antiquarian and historian his memory will long be preserved. His "Fœdera," which is a collection of all the public transactions, treaties, &c. of the kings of England with foreign princes, is esteemed one of our most authentic and valuable records, and is oftener referred to by the best English historians than perhaps any other book in the language. It was published at London in the beginning of the last century, in 17 vols. folio. Three volumes more were added by Sanderfon after Rymer's death. The whole were reprinted at the Hague, in 10 vols. 1739. They were abridged by Rapin in French, and inserted in Le Clerc's Bibliotheque, a translation of which was made by Mr. Stephen Whatley, and printed in one vol. folio. &c. 4 vols. 8vo. 1731, under the title of *Acta Regia*. Mr. Rymer died the 14th of December 1713, and was buried in the parish church of St. Clement's Danes. Some specimens of his poetry are preserved in the first volume of Mr. Nichols's Select Collection of Miscellaneous Poems, 1780.

RYNABAD, in *Geography*, a town of Bengal; 35 miles S.E. of Moorley.

RYNCHOPS, *the Skimmer*, in *Ornithology*, a genus of birds of the order Anseres, of which the generic character is, that the bill is straight, the upper mandible is much shorter than the under, the latter truncated at the apex; the tail is forked and shorter than the wings, nostrils linear, and the back toe small.

#### Species.

NIGRA; Black Skimmer, or Cut-water. The specific character is blackish, beneath white; bill red at the base; the lower mandible grooved; the front and chin are white; wings with a transverse white band; the two middle tail-feathers are black, the next edged with white; the legs are red, and it is about twenty inches long. It is found in divers parts of Asia and America. This bird is ever on the wing, sweeping the surface of the water, dipping its bill, or at least its under mandible, to scoop out the smaller fishes, on which it feeds. In stormy weather it frequents the shores, and is contented with oysters, and other shell-fish. There is a variety of a tawny colour, with a black bill.

RYNNTO, in *Geography*, a small island in the gulf of Bothnia, near the coast of Finland. N. lat. 60° 37'. E. long. 21° 46'.

RYNOORT, a town of Holland, on the Rhine; seven miles E. of Leyden.

RYOTS, the modern name by which the renters of land are distinguished in Hindoostan. In every part of India, where the native Hindoo princes retain dominion, these Ryots hold their possession by a lease, which may be considered as perpetual, and at a rate fixed by ancient surveyors

and valuations. This arrangement has been so long established, and accords so well with the ideas of the natives, concerning the distinctions of casts, and the functions allotted to each, that it has been inviolably maintained, in all the provinces subject either to Mahometans or Europeans; and to both it serves as the basis on which their whole system of finance is founded. In a more remote period, before the original institutions of India were subverted by foreign invaders, the industry of the husbandman, on which every member of the community depended for subsistence, was as secure, as the tenure, by which he held his lands, was equitable. Even war did not interrupt his labours or endanger his property. It was not uncommon, we are informed, that while two hostile armies were fighting a battle in one field, the peasants were ploughing or reaping in the next field in perfect tranquillity. (Strabo, lib. xv.) Under a form of government, which paid such attention to all the different orders of which the society is composed, particularly the cultivators of the earth, it is not wonderful that the ancients should describe the Indians as a most happy race of men; and that the most intelligent modern observers should celebrate the equity, the humanity, and mildness of Indian policy. A Hindoo rajah resembles more a father presiding in a numerous family of his own children, than a sovereign ruling over inferiors subject to his dominion. He endeavours to secure their happiness with vigilant solicitude; they are attached to him with the most tender affection and inviolable fidelity. We can hardly conceive men to be placed in any state more favourable to their acquiring all the advantages derived from social union. It is only when the mind is perfectly at ease, and neither feels nor dreads oppression, that it employs its active powers in forming numerous arrangements of police, for securing its enjoyments and increasing them. Many arrangements of this nature the Greeks, though accustomed to their own institutions, the most perfect at that time in Europe, observed and admired among the Indians, and mention them as instances of high civilization and improvement. There were established among the Indians three distinct classes of officers, one of which had it in charge to inspect agriculture, and every kind of country work. They measured the portions of land allotted to each renter. They had the custody of the *tanks*, or public reservoirs of water, without a regular distribution of which, the fields in a torrid climate cannot be rendered fertile. They marked out the course of the highways, along which, at certain distances, they erected stones, to measure the road and direct travellers. To officers of a second class was committed the inspection of the police in cities; their functions of course were many and various; some of which only we shall specify. They appropriated houses for the reception of strangers; they protected them from injury, provided for their subsistence, and, when seized with any disease, they appointed physicians to attend them; and, on the event of their death, they not only buried them with decency, but took charge of their effects, and re-iterated them to their relations. They kept exact registers of births and of deaths. They visited the public markets, and examined weights and measures. The third class of officers superintended the military department; but, as the objects to which their attention was directed are foreign from the subject of this article, it is unnecessary to enter into any detail with respect to them.

There is still the same attention to the construction and preservation of tanks, and the distribution of their waters. The direction of roads, and placing stones along them, is still an object of police. *Choultries*, or houses built for the accommodation of travellers, are frequent in every part

of the country, and are useful, as well as noble monuments of Indian munificence and humanity.

The precise mode, however, in which the Ryots of Hindoostan held their possessions, is a circumstance in its ancient political constitution, with respect to which gentlemen of superior discernment, who have resided long in the country, and filled some of the highest stations in government, have formed very different opinions. Some have imagined, that grants of land were made by the sovereign to villages or small communities, the inhabitants of which, under the direction of their own chiefs or heads-men, laboured it in common, and divided the produce of it among them in certain proportions. (Descript. de l'Inde, par M. Bernoulli, tom. ii. 223, &c.) Others maintain, that the property of land has been transferred from the crown to hereditary officers of great eminence and power, denominated *Zemindars*, who collect the rents from the Ryots, and parcel out the lands among them. Others contend, that the office of the *Zemindars* is temporary and ministerial, that they are merely collectors of revenue, removeable at pleasure, and the tenure by which the Ryots hold their possessions is derived immediately from the sovereign. This last opinion is supported, with great ability, by Mr. Grant, in an Inquiry into the Nature of Zemindary Tenures in the Landed Property of Bengal, &c. This question still continues to be agitated in Bengal, and such plausible arguments have been produced in support of the different opinions, that although it be a point extremely interesting, as the future system of British finance in India appears likely to hinge, in an essential degree, upon it, persons well acquainted with the state of India, have not been able to form a final and satisfactory opinion upon this subject. (Captain Kirkpatrick's Introd. to the Institutes of Ghazan Khan. New Asiatic Miscell. N<sup>o</sup> II. p. 130.) Though the sentiments of the Committee of Revenue, composed of persons eminent for their abilities, lean to a conclusion against the hereditary right of the *Zemindars* in the soil, yet the Supreme Council, in the year 1786, declined, for good reasons, to give any decisive judgment on a subject of such magnitude.

Mr. Rouse, in his ingenious and instructive Dissertation concerning the landed property of Bengal, adopts an opinion contrary to that of Mr. Grant, and maintains, with laudable candour and liberality of sentiment, that the *Zemindars* of Bengal possess their landed property by hereditary right. Dr. Robertson, in his "Historical Disquisition concerning India," suggests, that the possession of land was granted at first during pleasure, afterwards for life, and at length became perpetual and hereditary property. But even under this last form, when land is acquired either by purchase or inheritance, the manner in which the right of property is confirmed and rendered complete, in Europe by a charter, in India by a "Sunnud" from the sovereign, seems to point out what was its original state. According to each of the theories above-mentioned, the tenure and condition of the Ryots nearly resemble the description which our author has given of them. Their state, we learn from the accounts of intelligent observers, is as happy and independent as falls to the lot of any race of men employed in the cultivation of the earth. The ancient Greek and Roman writers, whose acquaintance with the interior parts of India was very imperfect, represent the fourth part of the annual produce of land as the general average of rent paid to the sovereign. Upon the authority of a popular author, who flourished in India prior to the Christian era, we may conclude, that a sixth part of the people's income was, in his time, the usual portion of the sovereign. (Saconata, act v. p. 53.) It is now

known, that what the sovereign receives from land varies greatly in different parts of the country, and is regulated by the fertility or barrenness of the soil, the nature of the climate, the abundance or scarcity of water, and many other obvious circumstances. By the account given of it, Dr. Robertson imagines that, in some districts, it has been raised beyond its due proportion. One circumstance with respect to the administration of revenue in Bengal merits notice, as it redounds to the honour of the emperor Akber, the wisdom of whose government has often been conspicuous. A general and regular assessment of revenue in Bengal was formed in his reign. All the lands were then valued, and the rent of each inhabitant and of each village ascertained. A regular gradation of accounts was established. The rents of the different inhabitants who lived in one neighbourhood being collected together, formed the account of a village; the rents of several villages being next collected into one view, formed the accounts of a larger portion of land. The aggregate of these accounts exhibited the rent of a district, and the sum total of the rents of all the districts in Bengal, formed the account of the revenue of the whole province. From the reign of Akber to the government of Jaffier Ali Cawn, A.D. 1757, the annual amount of revenue, and the modes of levying it, continued with little variation. But in order to raise the sum which he had stipulated to pay the English on his elevation, he departed from the wise arrangements of Akber; many new modes of assessment were introduced, and exactions multiplied. Robertson's India.

RYOZ, in *Geography*, a town of France, in the department of the Upper Saône; 11 miles N. of Besançon.

RYPOUR, a town of Hindoostan, in the circar of Gohud; 10 miles S.S.E. of Gwalior.—Also, a town of Hindoostan, in Bahar; 24 miles S.S.E. of Bahar.

RYPTICS, in *Medicine*. See RYPTICS.

RYR, in *Geography*, a town of Sweden, in West Gothland; seven miles N.E. of Uddevalla.

RYS, a lake of Denmark, in Norland.

RYSAGON, in the *Materia Medica*, a name by which some authors have called the *castumunar root*.

RYSBY, in *Geography*, a town of Sweden, in the province of Samland; 10 miles N. of Calmar.

RYSEMSEH, a town of Norway; 48 miles E.N.E. of Romfdal.

RYSEN, or RYSEN, a town of Holland, in the department of Overijssel, on the river Regge; 20 miles N.E. of Zutphen.

RYSSADIUM, in *Ancient Geography*, a town and port of Africa, in Mauritania Tingitana, on the coast of the Iberian ocean, between Septimia Extrema and the promontory Mesagonites, according to Ptolemy. It is named by Antonine Rufardus Colonia, and Rufardus by Pliay, who places it near the promontory "Solis."

RYSSADIUM, a promontory of Africa, in the Interior Libya, near the promontory Arsinarium, according to Ptolemy.

RYSSADIUS MONS, a mountain of Africa, in the Interior Libya, in which Ptolemy places the source of the river "Stachier."

RYSWICK, in *Geography*, a large village in Holland, situated between the Hague and Delft, where the prince of Orange had a palace; and remarkable for a treaty concluded here in 1697 between England, Germany, Holland, France, and Spain; 30 miles S.W. of Amsterdam, and two S.E. from the Hague.

RYVES, THOMAS, in *Biography*, born in the latter end of the 16th century, and educated at Winchester school, from whence he was sent to Oxford. He became celebrated as a civilian in Doctors' Commons, and in the court of Admiralty. At the accession of Charles I. he was made king's advocate, and was knighted. He died in 1651. He wrote several works, among which were "The Vicar's Plea;" "Historia Navalis Antiqua;" "Historia Navalis Media."

RYVES, BRUNO, an English divine, and near relation of the preceding. At the restoration of Charles II. he had the deanery of Windsor conferred on him. He was also secretary to Garter king at arms. He was author of "Mercurius Rusticus," or "The Country's Complaint," and divers other works, which were popular in their day.

RYVORDEN, in *Geography*, a small island in the North sea, near the coast of Norway. N. lat. 59° 27'.

RZECZYCA, a town of Lithuania, in the palatinate of Minsk, on the Dnieper; 140 miles S.E. of Minsk. N. lat. 52° 10'. E. long. 31° 24'.

RZEMIEN, a town of Poland, in the palatinate of Sandomirz; 36 miles S.S.W. of Sandomirz.
